Open problem session

Sep 12, 2023

Please bring your favourite (math) problems. Anyone with a problem to share will be given about 5 minutes to present it. We will also choose most of the speakers for the rest of the semester.

Gabriel Verret (University of Auckland, New Zealand)

Sept 19, 2023

Vertex-transitive graphs with large automorphism groups

Many results in algebraic graph theory can be viewed as upper bounds on the size of the automorphism group of graphs satisfying various hypotheses. These kinds of results have many applications. For example, Tutte's classical theorem on 3-valent arc-transitive graphs led to many other important results about these graphs, including enumeration, both of small order and in the asymptotical sense. This naturally leads to trying to understand barriers to this type of results, namely graphs with large automorphism groups. We will discuss this, especially in the context of vertex-transitive graphs of fixed valency. We will highlight the apparent dichotomy between graphs with automorphism group of polynomial (with respect to the order of the graph) size, versus ones with exponential size.

Sedanur Albayrak (University of Calgary)

Sept 26, 2023

Quantitative estimates for the size of an intersection of sparse automatic sets

In 1979, Erdős conjectured that for $k \geq 9$, 2^k is not the sum of distinct powers of 3. That is, the set of powers of two (which is 2-automatic) and the 3-automatic set consisting of numbers whose ternary expansions omit 2 has finite intersection. In the theory of automata, a theorem of Cobham (1969) says that if k and ℓ are two multiplicatively independent natural numbers then a subset of the natural numbers that is both k - and ℓ -automatic is eventually periodic. A multidimensional extension was later given by Semenov (1977). Motivated by Erdős' conjecture and in light of Cobham's theorem, we give a quantitative version of the Cobham-Semenov theorem for sparse automatic sets, showing that the intersection of a sparse k -automatic subset of \mathbb{N}^d and a sparse ℓ -automatic subset of \mathbb{N}^d is finite. Moreover, we give effectively computable upper bounds on the size of the intersection in terms of data from the automata that accept these sets.

Kübra Benli (Math and CS, U of Lethbridge)

Oct 3, 2023

Sums of proper divisors with missing digits

In 1992, Erdős, Granville, Pomerance, and Spiro conjectured that if \mathcal{A} is a set of integers with asymptotic density zero then the preimage of \mathcal{A} under $s(n)$, sum-of-proper-divisors function, also has asymptotic density zero. In this talk, we will discuss the verification of this conjecture when \mathcal{A} is taken to be the set of integers with missing digits (also known as ellipsephic integers) by giving a quantitative estimate on the size of the set $s^{-1}(\mathcal{A})$. This is joint work with Giulia Cesana, Cécile Dartyg, Charlotte Dombrowsky and Lola Thompson.

Wanlin Li (Washington University, St. Louis)

Oct 12, 2023

Basic reductions of abelian varieties

Given an abelian variety A defined over a number field, a conjecture attributed to Serre states that the set of primes at which A admits ordinary reduction is of positive density. This conjecture had been proved for elliptic curves (Serre, 1977), abelian surfaces (Katz 1982, Sawin 2016) and certain higher dimensional abelian varieties (Pink 1983, Fite 2021, etc).

In this talk, we will discuss ideas behind these results and recent progress for abelian varieties with non-trivial endomorphisms, including the case where A has almost complex multiplication by an abelian CM field, based on joint work with Cantoral-Farfan, Mantovan, Pries, and Tang.

Apart from ordinary reduction, we will also discuss the set of primes at which an abelian variety admits basic reduction, generalizing a result of Elkies on the infinitude of supersingular primes for elliptic curves. This is joint work with Mantovan, Pries, and Tang.

Zenchao Ge (University of Waterloo)

Oct 17, 2023

A Weyl-type inequality for irreducible elements in function fields, with applications

We establish a Weyl-type estimate for exponential sums over irreducible elements in function fields. As an application, we generalize an equidistribution theorem of Rhin. Our estimate works for polynomials with degree higher than the characteristic of the field, a barrier to the traditional Weyl differencing method. In this talk, we briefly introduce Lê-Liu-Wooley's original argument for ordinary Weyl sums (taken over all elements), and how we generalize it to estimate bilinear exponential sums with general coefficients. This is joint work with Jérémy Campagne (Waterloo), Thái Hoàng Lê (Mississippi) and Yu-Ru Liu (Waterloo).

Yu-Ru Liu (University of Waterloo)

Oct 25, 2023

Fermat vs Waring: an introduction to number theory in function fields

Let \mathbb{Z} be the ring of integers, and let $\mathbb{F}_p[t]$ be the ring of polynomials in one variable defined over the finite field \mathbb{F}_p of p elements. Since the characteristic of \mathbb{Z} is 0, while that of $\mathbb{F}_p[t]$ is the positive prime number p , it is a striking theme in arithmetic that these two rings faithfully resemble each other. The study of the similarity and difference between \mathbb{Z} and $\mathbb{F}_p[t]$ lies in the field that relates number fields to function fields. In this talk, we will investigate some Diophantine problems in the settings of \mathbb{Z} and $\mathbb{F}_p[t]$, including Fermat's Last Theorem and Waring's problem.

Joy Morris (Math and CS, U of Lethbridge)

Oct 31, 2023

Easy detection of (Di)Graphical Regular Representations

Graphical and Digraphical Regular Representations (GRRs and DRRs) are a concrete way to visualise the regular action of a group, using graphs. More precisely, a GRR or DRR on the group G is a (di)graph whose automorphism group is isomorphic to the regular action of G on itself by right-multiplication.

For a (di)graph to be a DRR or GRR on G , it must be a Cayley (di)graph on G . Whenever the group G admits an automorphism that fixes the connection set of the Cayley (di)graph setwise, this induces a nontrivial graph automorphism that fixes the identity vertex, which means that the (di)graph is not a DRR or GRR. Checking whether or not there is any group automorphism that fixes a particular connection set can be done very quickly and easily compared with checking whether or not any nontrivial graph automorphism fixes some vertex, so it would be nice to know if there are circumstances under which the simpler test is enough to guarantee whether or not the Cayley graph is a GRR or DRR. I will present a number of results on this question.

This is based on joint work with Dave Morris and with Gabriel Verret.

Abbas Maarefparvar (Math and CS, U of Lethbridge)

Nov 7, 2023

Some Pólya Fields of Small Degrees

Historically, the notion of Pólya fields dates back to some works of George Pólya and Alexander Ostrowski, in 1919, on entire functions with integer values at integers; a number field K with ring of integers \mathcal{O}_K is called a Pólya field whenever the \mathcal{O}_K -module $\{f \in K[X] : f(\mathcal{O}_K) \subseteq \mathcal{O}_K\}$ admits an \mathcal{O}_K -basis with exactly one member from each degree. Pólya fields can be thought of as a generalization of number fields with class number one, and their classification of a specific degree has become recently an active research subject in algebraic number theory. In this talk, I will present some criteria for K to be a Pólya field. Then I will give some results concerning Pólya fields of degrees 2, 3, and 6.

Sreerupa Bhattacharjee (Math and CS, U of Lethbridge)

Nov 21, 2023

A survey of Büthe's method for estimating prime counting functions

This talk will begin with a study on explicit bounds for $\psi(x)$ starting with the work of Rosser in 1941. It will also cover various improvements over the years including the works of Rosser and Schoenfeld, Dusart, Faber-Kadiri, Platt-Trudgian, Büthe, and Fiori-Kadiri-Swidinsky. In the second part of this talk, I will provide an overview of my master's thesis which is a survey on 'Estimating $\pi(x)$ and Related Functions under Partial RH Assumptions' by Jan Büthe. This article provides the best known bounds for $\psi(x)$ for small values of x in the interval $[e^{50}, e^{3000}]$. A distinctive feature of this paper is the use of Logan's function and its Fourier Transform. I will be presenting the main theorem in Büthe's paper regarding estimates for $\psi(x)$ with other necessary results required to understand the proof.

Ha Tran (Concordia University of Edmonton)

Nov 28, 2023

The size function for imaginary cyclic sextic fields

The size function h^0 for a number field is analogous to the dimension of the Riemann-Roch spaces of divisors on an algebraic curve. Van der Geer and Schoof conjectured that h^0 attains its maximum at the trivial class of Arakelov divisors if that field is Galois over \mathbb{Q} or over an imaginary quadratic field. This conjecture was proved for all number fields with the unit group of rank 0 and 1, and also for cyclic cubic fields which have unit group of rank two. In this talk, we will discuss the main idea to prove that the conjecture also holds for totally imaginary cyclic sextic fields, another class of number fields with unit group of rank two. This is joint work with Peng Tian and Amy Feaver.

Spring 2023

A walk on Legendre paths

Jan 9, 2023

The Legendre symbol is one of the most basic, mysterious and extensively studied objects in number theory. It is a multiplicative function that encodes information about whether an integer is a square modulo an odd prime p . The Legendre symbol was introduced by Adrien-Marie Legendre in 1798, and has since found countless applications in various areas of mathematics as well as in other fields including cryptography. In this talk, we shall explore what we call “Legendre paths”, which encode information about the values of the Legendre symbol. The Legendre path modulo p is defined as the polygonal path in the plane formed by joining the partial sums of the Legendre symbol modulo p . In particular, we will attempt to answer the following questions as we vary over the primes p : how are these paths distributed? how do their maximums behave? and what proportion of the path is above the real axis? Among our results, we prove that these paths converge in law, in the space of continuous functions, to a certain random Fourier series constructed using Rademacher random multiplicative functions. Part of this work is joint with Ayesha Hussain.

Neelam Kandhil (Institute of Mathematical Sciences, Chennai, India)
On linear independence of Dirichlet L-values

Jan 16, 2023

It is an open question of Baker whether the Dirichlet L-values at 1 with fixed modulus are linearly independent over the rational numbers. The best-known result is due to Baker, Birch and Wirsing, which affirms this when the modulus of the associated Dirichlet character is co-prime to its Euler’s phi value. In this talk, we will discuss an extension of this result to any arbitrary family of moduli. The interplay between the resulting ambient number fields brings new technical issues and complications hitherto absent in the context of a fixed modulus. We will also investigate the linear independence of such values at integers greater than 1.

Antonella Perucca (University of Luxembourg)
Recent advances in Kummer theory

Jan 23, 2023

Kummer theory is a classical theory about radical extensions of fields in the case where suitable roots of unity are present in the base field. Motivated by problems close to Artin’s primitive root conjecture, we have investigated the degree of families of general Kummer extensions of number fields, providing parametric closed formulas. We present a series of papers that are in part joint work with Christophe Debry, Fritz Hörmann, Pietro Sogbba, and Sebastiano Tronto.

Oussama Hamza (University of Western Ontario)

Jan 30, 2023

Filtrations, arithmetic and explicit examples in an equivariant context

Pro- p groups arise naturally in number theory as quotients of absolute Galois groups over number fields. These groups are quite mysterious. During the 60's, Koch gave a presentation of some of these quotients. Furthermore, around the same period, Jennings, Golod, Shafarevich and Lazard introduced two integer sequences (a_n) and (c_n) , closely related to a special filtration of a finitely generated pro- p group G , called the Zassenhaus filtration. These sequences give the cardinality of G , and characterize its topology. For instance, we have the well-known Gocha's alternative (Golod and Shafarevich): There exists an integer n such that $a_n = 0$ (or c_n has a polynomial growth) if and only if G is a Lie group over p -adic fields.

In 2016, Minac, Rogelstad and Tan inferred an explicit relation between a_n and c_n . Recently (2022), considering geometrical ideas of Filip and Stix, Hamza got more precise relations in an equivariant context: when the automorphism group of G admits a subgroup of order a prime q dividing $p - 1$.

In this talk, we present equivariant relations inferred by Hamza (2022) and give explicit examples in an arithmetical context.

Cristhian Garay (CIMAT Guanajuato, Mexico)

Feb 6, 2023

Generalized valuations and idempotization of schemes

Classical valuation theory has proved to be a valuable tool in number theory, algebraic geometry and singularity theory. For example, one can enrich spectra of rings with new points coming from valuations defined on them and taking values in totally ordered abelian groups.

Totally ordered groups are examples of idempotent semirings, and generalized valuations appear when we replace totally ordered abelian groups with more general idempotent semirings. An important example of idempotent semiring is the tropical semifield.

As an application of this set of ideas, we show how to associate an idempotent version of the structure sheaf of a scheme, which behaves particularly well with respect to idempotization of closed subschemes. This is a joint work with Félix Baril Boudreau.

Cristhian Garay (CIMAT Guanajuato, Mexico)

Feb 6 and 9, 2023

An invitation to the algebraic geometry over idempotent semirings (Minicourse)

Idempotent semirings have been relevant in several branches of applied mathematics, like formal languages and combinatorial optimization. They were brought recently to pure mathematics thanks to its link with tropical geometry, which is a relatively new branch of mathematics that has been useful in solving some problems and conjectures in classical algebraic geometry. However, up to now we do not have a proper algebraic formalization of what could be called "Tropical Algebraic Geometry", which is expected to be the geometry arising from idempotent semirings. In this mini course we aim to motivate the necessity for such theory, and we recast some old constructions in order theory in terms of commutative algebra of semirings and modules over them.

Kelly Emmrich (Colorado State University)
The principal Chebotarev density theorem

Feb 13, 2023

Let K/k be a finite Galois extension. We define a principal version of the Chebotarev density theorem which represents the density of prime ideals of k that factor into a product of principal prime ideals in K . We find explicit equations to express the principal density in terms of the invariants of K/k and give an effective bound which can be used to verify the non-splitting of the Hilbert exact sequence.

Florent Jouve (Université de Bordeaux, France)
Fluctuations in the distribution of Frobenius automorphisms in number field extensions

Feb 27, 2023

Given a Galois extension of number fields L/K , the Chebotarev Density Theorem asserts that, away from ramified primes, Frobenius automorphisms equidistribute in the set of conjugacy classes of $\text{Gal}(L/K)$. In this talk we report on joint work with D. Fiorilli in which we study the variations of the error term in Chebotarev's Theorem as L/K runs over certain families of extensions. We shall explain some consequences of this analysis: regarding first "Linnik type problems" on the least prime ideal in a given Frobenius set, and second, the existence of unconditional "Chebyshev biases" in the context of number fields. Time permitting we will mention joint work with R. de La Bretèche and D. Fiorilli in which we go one step further and study moments of the distribution of Frobenius automorphisms.

John Voight (Dartmouth College, USA)
A norm refinement of Bezout's Lemma, and quaternion orders

Mar 6, 2023

Given coprime integers a, b , the classical identity of Bezout provides integers u, v such that $au - bv = 1$. We consider refinements to this identity, where we ask that u, v are norms from a quadratic extension. We then find ourselves counting optimal embeddings of a quadratic order in a quaternion order, for which we give explicit formulas in many cases. This is joint work with Donald Cartwright and Xavier Roulleau.

Renate Scheidler (University of Calgary)
Orienteering on Supersingular Isogeny Volcanoes Using One Endomorphism

Mar 13, 2023

Elliptic curve isogeny path finding has many applications in number theory and cryptography. For supersingular curves, this problem is known to be easy when one small endomorphism or the entire endomorphism ring are known. Unfortunately, computing the endomorphism ring, or even just finding one small endomorphism, is hard. How difficult is path finding in the presence of one (not necessarily small) endomorphism? We use the volcano structure of the oriented supersingular isogeny graph to answer this question. We give a classical algorithm for path finding that is subexponential in the degree of the endomorphism and linear in a certain class number, and a quantum algorithm for finding a smooth isogeny (and hence also a path) that is subexponential in the discriminant of the endomorphism. A crucial tool for navigating supersingular oriented isogeny volcanoes is a certain class group action on oriented elliptic curves which generalizes the well-known class group action in the setting of ordinary elliptic curves.

Joshua Males (University of Manitoba)

Mar 20, 2023

Forgotten conjectures of Andrews for Nahm-type sums

In his famous '86 paper, Andrews made several conjectures on the function $\sigma(q)$ of Ramanujan, including that it has coefficients (which count certain partition-theoretic objects) whose sup grows in absolute value, and that it has infinitely many Fourier coefficients that vanish. These conjectures were famously proved by Andrews-Dyson-Hickerson in their '88 Inventiones paper, and the function σ has been related to the arithmetic of $\mathbb{Z}[\sqrt{6}]$ by Cohen (and extensions by Zwegers), and is an important first example of quantum modular forms introduced by Zagier.

A closer inspection of Andrews' '86 paper reveals several more functions that have been a little left in the shadow of their sibling σ , but which also exhibit extraordinary behaviour. In an ongoing project with Folsom, Rolin, and Storzer, we study the function $\nu_1(q)$ which is given by a Nahm-type sum and whose coefficients count certain differences of partition-theoretic objects. We give explanations of four conjectures made by Andrews on ν_1 , which require a blend of novel and well-known techniques, and reveal that ν_1 should be intimately linked to the arithmetic of the imaginary quadratic field $\mathbb{Q}[\sqrt{-3}]$.

Douglas Ulmer (University of Arizona)

Mar 27, 2023

 p -torsion of Jacobians for unramified $\mathbb{Z}/p\mathbb{Z}$ -covers of curves

It is a classical problem to understand the set of Jacobians of curves among all abelian varieties, i.e., the image of the map $M_g \rightarrow A_g$ which sends a curve X to its Jacobian J_X . In characteristic p , A_g has interesting filtrations, and we can ask how the image of M_g interacts with them. Concretely, which groups schemes arise as the p -torsion subgroup $J_X[p]$ of a Jacobian? We consider this problem in the context of unramified $\mathbb{Z}/p\mathbb{Z}$ covers $Y \rightarrow X$ of curves, asking how $J_Y[p]$ is related to $J_X[p]$. Translating this into a problem about de Rham cohomology yields some results using classical ideas of Chevalley and Weil. This is joint work with Bryden Cais.

Harald Andrés Helfgott (University of Göttingen, Germany)

Apr 3, 2023

Expansion, divisibility and parity

We will discuss a graph that encodes the divisibility properties of integers by primes. We prove that this graph has a strong local expander property almost everywhere. We then obtain several consequences in number theory, beyond the traditional parity barrier, by combining our result with Matomaki-Radziwiłł. For instance: for lambda the Liouville function (that is, the completely multiplicative function with $\lambda(p) = -1$ for every prime),

$$\frac{1}{\log x} \sum_{n \leq x} \frac{\lambda(n)\lambda(n+1)}{n} = O\left(\frac{1}{\sqrt{\log \log x}}\right),$$

which is stronger than well-known results by Tao and Tao-Teravainen. We also manage to prove, for example, that $\lambda(n+1)$ averages to 0 at almost all scales when n restricted to have a specific number of prime divisors $\Omega(n) = k$, for any "popular" value of k (that is, $k = \log \log N + O(\sqrt{\log \log N})$ for $n \leq N$).

Fall 2022

Open problem session

Sep 12, 2022

Dang-Khoa Nguyen (University of Calgary)

Sep 26, 2022

Height gaps for coefficients of D-finite power series

A power series $f(x_1, \dots, x_m) \in \mathbb{C}[[x_1, \dots, x_m]]$ is said to be D-finite if all the partial derivatives of f span a finite dimensional vector space over the field $\mathbb{C}(x_1, \dots, x_m)$. For the univariate series $f(x) = \sum a_n x^n$, this is equivalent to the condition that the sequence (a_n) is P-recursive meaning a non-trivial linear recurrence relation of the form:

$$P_d(n)a_{n+d} + \dots + P_0(n)a_n = 0$$

where the P_i 's are polynomials. In this talk, we consider D-finite power series with algebraic coefficients and discuss the growth of the Weil height of these coefficients.

Debanjana Kundu (University of British Columbia)

Oct 3, 2022

Studying Hilbert's 10th problem via explicit elliptic curves

In 1900, Hilbert posed the following problem: "Given a Diophantine equation with integer coefficients: to devise a process according to which it can be determined in a finite number of operations whether the equation is solvable in (rational) integers."

Building on the work of several mathematicians, in 1970, Matiyasevich proved that this problem has a negative answer, i.e., such a general 'process' (algorithm) does not exist.

In the late 1970's, Denef-Lipshitz formulated an analogue of Hilbert's 10th problem for rings of integers of number fields.

In recent years, techniques from arithmetic geometry have been used extensively to attack this problem. One such instance is the work of García-Fritz and Pasten (from 2019) which showed that the analogue of Hilbert's 10th problem is unsolvable in the ring of integers of number fields of the form $\mathbb{Q}(\sqrt[3]{p}, \sqrt{-q})$ for positive proportions of primes p and q . In joint work with Lei and Sprung, we improve their proportions and extend their results in several directions. We achieve this by using multiple elliptic curves, and by replacing their Iwasawa theory arguments by a more direct method.

Elchin Hasanalizade (Math and CS, U of Lethbridge)

Oct 17, 2022

Sums of Fibonacci numbers close to a power of 2

The Fibonacci sequence $(F_n)_{n \geq 0}$ is the binary recurrence sequence defined by $F_0 = F_1 = 1$ and

$$F_{n+2} = F_{n+1} + F_n \text{ for all } n \geq 0.$$

There is a broad literature on the Diophantine equations involving the Fibonacci numbers. In this talk, we will study the Diophantine inequality

$$|F_n + F_m - 2^a| < 2^{a/2}$$

in positive integers n, m and a with $n \geq m$. The main tools used are lower bounds for linear forms in logarithms due to Matveev and Dujella-Pethö version of the Baker-Davenport reduction method in diophantine approximation.

Dave Morris (Math and CS, U of Lethbridge)

Oct 24, 2022

On vertex-transitive graphs with a unique hamiltonian circle

We will discuss graphs that have a unique hamiltonian cycle and are vertex-transitive, which means there is an automorphism that takes any vertex to any other vertex. Cycles are the only examples with finitely many vertices, but the situation is more interesting for infinite graphs. (Infinite graphs do not have “hamiltonian cycles,” but there are natural analogues.) The case where the graph has only finitely many ends is not difficult, but we do not know whether there are examples with infinitely many ends. This is joint work in progress with Bobby Miraftab.

Hugo Chapdelaine (Université Laval)

Oct 31, 2022

Computation of Galois groups via permutation group theory

In this talk we will present a method to study the Galois group of certain polynomials defined over \mathbb{Q} . Our approach is similar in spirit to some previous work of F. Hajir, who studied, more than a decade ago, the generalized Laguerre polynomials using a similar approach. For example this method seems to be well suited to study the Galois groups of Jacobi polynomials (a classical family of orthogonal polynomials with two parameters — three if we include the degree). Given a polynomial $f(x)$ with rational coefficients of degree N over \mathbb{Q} , the idea consists in finding a good prime p and look at the Newton polygon of f at p . Then combining the Galois theory of local field over \mathbb{Q}_p and some classical results of the theory of permutation of groups we sometimes succeed in showing that the Galois group of f is not solvable or even isomorphic to A_N or S_N ($N \geq 5$).

The existence of a good prime p is subtle. In order to get useful results one would need to have some “effective prime existence results”. As an illustration, we would like to have an explicit constant C (not too big) such that for any $N > C$, there exists a prime p in the range $N < p < \frac{3N}{2}$ such that $\gcd(p-1, N) = 1$ or 2 (depending on the parity of N). Such a result is not so easy to get when N is divisible by many distinct and small primes. We hope that such effective prime existence results are within the reach of the current techniques used in analytic number theory.

Julie Desjardins (University of Toronto)

Nov 7, 2022

Torsion points and concurrent lines on Del Pezzo surfaces of degree one

The blow up of the anticanonical base point on X , a del Pezzo surface of degree 1, gives rise to a rational elliptic surface E with only irreducible fibers. The sections of minimal height of E are in correspondence with the 240 exceptional curves on X . A natural question arises when studying the configuration of those curves:

If a point of X is contained in “many” exceptional curves, is it torsion on its fiber on E ?

In 2005, Kuwata proved for del Pezzo surfaces of degree 2 (where there are 56 exceptional curves) that if “many” equals 4 or more, then yes. In a joint paper with Rosa Winter, we prove that for del Pezzo surfaces of degree 1, if “many” equals 9 or more, then yes. Moreover, we find counterexamples where a torsion point lies at the intersection of 7 exceptional curves.

Soleh Bolvardizadeh (Math and CS, U of Lethbridge)

Nov 21, 2022

On the Quality of the ABC-Solutions

The quality of the triplet (a, b, c) , where $\gcd(a, b, c) = 1$, satisfying $a + b = c$ is defined as

$$q(a, b, c) = \frac{\max\{\log |a|, \log |b|, \log |c|\}}{\log \text{rad}(|abc|)},$$

where $\text{rad}(|abc|)$ is the product of distinct prime factors of $|abc|$. We call such a triplet an *ABC-solution*. The *ABC-conjecture* states that given $\epsilon > 0$ the number of *ABC-solutions* (a, b, c) with $q(a, b, c) \geq 1 + \epsilon$ is finite.

In the first part of this talk, under the *ABC-conjecture*, we explore the quality of certain families of *ABC-solutions* formed by terms in Lucas and associated Lucas sequences. We also introduce, unconditionally, a new family of *ABC-solutions* that has quality > 1 .

In the remainder of the talk, we prove a conjecture of Erdős on the solutions of the Brocard-Ramanujan equation

$$n! + 1 = m^2$$

by assuming an explicit version of the *ABC-conjecture* proposed by Baker.

Mathieu Dutour (University of Alberta)

Nov 28, 2022

Theta-finite pro-Hermitian vector bundles from loop groups elements

In the finite-dimensional situation, Lie’s third theorem provides a correspondence between Lie groups and Lie algebras. Going from the latter to the former is the more complicated construction, requiring a suitable representation, and taking exponentials of the endomorphisms induced by elements of the group.

As shown by Garland, this construction can be adapted for some Kac-Moody algebras, obtained as (central extensions of) loop algebras. The resulting group is called a loop group. One also obtains a relevant infinite-rank Chevalley lattice, endowed with a metric. Recent work by Bost and Charles provide a natural setting, that of pro-Hermitian vector bundles and theta invariants, in which to study these objects related to loop groups. More precisely, we will see in this talk how to define theta-finite pro-Hermitian vector bundles from elements in a loop group. Similar constructions are expected, in the future, to be useful to study loop Eisenstein series for number fields.

This is joint work with Manish M. Patnaik.

Alexandra Florea (University of California – Irvine)

Dec 5, 2022

Negative moments of the Riemann zeta-function

I will talk about recent work towards a conjecture of Gonek regarding negative shifted moments of the Riemann zeta-function. I will explain how to obtain asymptotic formulas when the shift in the Riemann zeta function is big enough, and how we can obtain non-trivial upper bounds for smaller shifts. I will also discuss some applications to the question of obtaining cancellation of averages of the Mobius function. Joint work with H. Bui.

Spring 2022

Open problem session

Jan 24, 2022

Please bring your favourite (math) problems. Anyone with a problem to share will be given about 5 minutes to present it. We will also choose most of the speakers for the rest of the semester.

Ertan Elma (University of Waterloo and U of Lethbridge)
Some identities concerning Dirichlet L -functions

Feb 7, 2022

Let χ be a nonprincipal Dirichlet character modulo a prime number $p \geq 3$ and $L(s, \chi)$ denote the Dirichlet L -function associated with the character χ . Define

$$\mathcal{M}(-s, \chi) := \frac{2}{p-1} \sum_{\substack{\psi \pmod{p} \\ \psi(-1)=-1}} L(1, \psi) L(-s, \chi\bar{\psi}), \quad \left(0 < \Re(s) < \frac{1}{2}\right)$$

and

$$\Delta(s, \chi) := \sum_{n=2}^{\infty} \frac{\chi(n)\Delta(n)}{n^s}, \quad (\Re(s) > 2)$$

where $\Delta(n)$ is the error term in the Prime Number Theorem given by

$$\Delta(n) = \sum_{m \leq n} \Lambda(m) - \frac{\Lambda(n)}{2} - n$$

and $\Lambda(\cdot)$ stands for the von Mangoldt function.

In this talk, we will obtain some identities for $\mathcal{M}(-s, \chi)$ and $\Delta(s, \chi)$. These identities show that $\mathcal{M}(-s, \chi)$ is related to $L(1-s, \chi)$ for $0 < \Re(s) < \frac{1}{2}$, and $\Delta(s, \chi)$ is related to the zeros of the Dirichlet L -functions $L(s, \chi\psi)$ where $\psi(-1) = -1$ and $\frac{1}{2} < \Re(s) < 1$, if such zeros exist.

No seminars while faculty was on strike February 10 to March 21.

Shamil Asgarli (University of British Columbia)
On the proportion of transverse-free curves

Mar 28, 2022

Given a smooth plane curve C defined over an arbitrary field k , we say that C is transverse-free if it has no transverse lines defined over k . If k is an infinite field, then Bertini's theorem guarantees the existence of a transverse line defined over k , and so the transverse-free condition is interesting only in the case when k is a finite field F_q . After fixing a finite field F_q , we can ask the following question: For each degree d , what is the fraction of degree d transverse-free curves among all the degree d curves? In this talk, we will investigate an asymptotic answer to the question as d tends to infinity. This is joint work with Brian Freidin.

From the Birch and Swinnerton-Dyer conjecture to Nagao's conjecture

Let E be an elliptic curve over \mathbb{Q} , and let a_p be the Frobenius trace for each prime p . In 1965, Birch and Swinnerton-Dyer formulated a conjecture which implies the convergence of the Nagao-Mestre sum

$$\lim_{x \rightarrow \infty} \frac{1}{\log x} \sum_{p < x} \frac{a_p \log p}{p} = -r + \frac{1}{2},$$

where r is the order of the zero of the L -function of E at $s = 1$, which is predicted to be the Mordell-Weil rank of $E(\mathbb{Q})$. We show that if the above limit exists, then the limit equals $-r + \frac{1}{2}$, and study the connections to the Riemann hypothesis for E . We also relate this to Nagao's conjecture for elliptic curves. Furthermore, we discuss a generalization of the above results for the Selberg classes and hence (conjecturally) for the L -function of abelian varieties and graphs.

Erdős-Ko-Rado properties of pseudo-Paley graphs of square order

Paley graphs connect many branches of mathematics, notably combinatorics and number theory. Inspired by the Erdős-Ko-Rado (EKR) theorem for Paley graphs of square order (first proved by Blokhuis) and recent development of the study of EKR-type results, we study the EKR property, the EKR-module property, and the strict-EKR property of pseudo-Paley graphs from unions of cyclotomic classes using a mixture of ideas from number theory, finite geometry, and combinatorics. In particular, we extend the EKR theorem for Paley graphs to several families of pseudo-Paley graphs and solve a problem proposed by Godsil and Meagher.

The talk is based on joint work with Shamil Asgarli, Sergey Goryainov, and Huiqiu Lin.

Andriaherimanana Sarobidy Razafimahatratra (University of Regina)

EKR problems for permutation groups

Given a finite transitive permutation group $G \leq \text{Sym}(\Omega)$ and a set of permutations $\mathcal{F} \subset G$, we say that \mathcal{F} is *intersecting* if any two elements of \mathcal{F} agree on an element of Ω . The *intersection density* of an intersecting set \mathcal{F} of G is

$$\rho(\mathcal{F}) := |\mathcal{F}| \left(\frac{|G|}{|\Omega|} \right)^{-1}$$

and the *intersection density* of G is

$$\rho(G) = \max \{ \rho(\mathcal{F}) \mid \mathcal{F} \subset G \text{ is intersecting} \}.$$

It was conjectured by Meagher, Razafimahatratra and Spiga in [On triangles in derangement graphs, *J. Combin. Theory Ser. A*, 180:105390, 2021] that if $G \leq \text{Sym}(\Omega)$ is transitive of degree pq , where p and q are odd primes, then $\rho(G) = 1$. I will talk about some recent progress on this conjecture for primitive groups.

Anthony Bonato (Ryerson University)
Pursuit-evasion games on graphs

Sep 29, 2021

In pursuit-evasion games, a set of pursuers attempts to locate, eliminate, or contain an evader in a network. The rules, specified from the outset, greatly determine the difficulty of the questions posed above. For example, the evader may be visible, but the pursuers may have limited movement speed, only moving to nearby vertices adjacent to them.

Central to pursuit-evasion games is the idea of optimizing certain parameters, whether they are the search number, burning number, or localization number, for example. We report on progress in several pursuit-evasion games on graphs and conjectures arising from their analysis. Finding the values, bounds, and algorithms to compute these graph parameters leads to topics intersecting graph theory, the probabilistic method, and geometry.

Raghu Pantangi (Math and CS, U of Lethbridge)
EKR-Module Property

Oct 6, 2021

Let G be a finite group acting transitively on X . We say $g, h \in G$ are intersecting if gh^{-1} fixes a point in X . A subset S of G is said to be an intersecting set if every pair of elements in S intersect. Cosets of point stabilizers are canonical examples of intersecting sets. The group action version of the classical Erdős-Ko-Rado problem asks about the size and characterization of intersecting sets of maximum possible size. A group action is said to satisfy the EKR property if the size of every intersecting set is bounded above by the size of a point stabilizer. A group action is said to satisfy the strict-EKR property if every maximum intersecting set is a coset of a point stabilizer. It is an active line of research to find group actions satisfying these properties. It was shown that all 2-transitive satisfy the EKR property. While some 2-transitive groups satisfy the strict-EKR property, not all of them do. However a recent result shows that all 2-transitive groups satisfy the slightly weaker “EKR-module property” (EKRM), that is, the characteristic vector of a maximum intersecting set is a linear span of characteristic vectors of cosets of point stabilizers. We will discuss about a few more infinite classes of group actions that satisfy the EKRM property. I will also provide a few non-examples and a characterization of the EKRM property using characters of G .

Mohsen Aliabadi (Iowa State University)
Matchable subsets in groups and their linear analogues

Oct 13, 2021

In this talk, we introduce the notions of matching matrices in groups and vector spaces, which lead to some necessary conditions for existence of acyclic matching in abelian groups and its linear analogue. We also discuss the linear local matching property in field extensions to find a dimension criterion for linear locally matchable bases. We provide an upper bound for the dimension of primitive subspaces in a separable field extension. We finally provide an application of matchings about the fundamental theorem of algebra. Our tools mix combinatorics and linear algebra.

Arc-disjoint hamiltonian dipaths in toroidal digrids

A directed graph H consists of a set $V(H)$ of vertices together with a subset $A(H)$ of $V(H) \times V(H)$ which are called arcs. A *hamiltonian dipath* in a digraph is a dipath that visits each vertex exactly once. The *Cartesian product* $H_1 \square H_2$ of two digraphs H_1 and H_2 is the digraph with vertex set $V(H_1) \times V(H_2)$ where the vertex (u_1, v_1) is joined to (u_2, v_2) by an arc if and only if either $u_1 = u_2$ and $v_1v_2 \in A(H_2)$ or $v_1 = v_2$ and $u_1u_2 \in A(H_1)$. The Cartesian product $C_m \square C_n$, where C_m and C_n are two dicycles, is called the toroidal digrid with m rows and n columns. In this talk, we see that there exist two arc-disjoint hamiltonian dipaths in every toroidal digrid.

Nima Hoda (École Normale Supérieure, France)

Oct 27, 2021

Shortcut graphs and groups

Shortcut graphs are graphs in which long enough cycles cannot embed without metric distortion. Shortcut groups are groups which act properly and cocompactly on shortcut graphs. These notions unify a surprisingly broad family of graphs and groups of interest in geometric group theory and metric graph theory including: systolic and quadric groups (in particular finitely presented $C(6)$ and $C(4)$ - $T(4)$ small cancellation groups), cocompactly cubulated groups, hyperbolic groups, Coxeter groups and the Baumslag-Solitar group $BS(1, 2)$. Most of these examples satisfy a strong form of the shortcut property. I will discuss some of these examples as well as some general constructions and properties of shortcut graphs and groups.

Connor Riddlesden (Math and CS, U of Lethbridge)

Nov 3, 2021

Automorphism and tree-decomposition

Harary and Sabidussi were the first to study the automorphisms of repeated graphs using the wreath product. Later Hemminger would go on to provide necessary and sufficient conditions for these of repeated automorphisms through the introduction of smorphisms and partitions of graphs. This notion of the wreath product tends to vary depending on the author, and comes under many different guises, including both the lexicographic product and gruppenkranz. We seek to find a generalised/alternate form of this notion and the theorem, to describe the automorphisms of any arbitrary finite connected graph G using its symmetries and tree decomposition. One method for doing this is by studying the vertex connectivity of a graph $\kappa(G)$, and the associated separating sets with size equal to $\kappa(G)$. Following this we can decompose the graphs into blocks based upon these separating sets and construct the tree decomposition. Then we conjecture that the automorphisms of G will be: the direct product of the automorphism of elements (excluding those in a separating set) in each block, with those automorphisms that are compatible with those in the separating set; in addition, to the semidirect product of a subset of the tree decompositions. For the case in which the vertex connectivity is one, we will present the definitive results which are currently in the process of being proved. For higher dimensional cases of vertex connectivity, we will present some of our latest findings and updated conjectures.

Nov 10, 2021

Co-maximal graphs of subgroups

Associating graphs with groups date back to Arthur Cayley. In this lecture, we will discuss about another graph, called co-maximal subgroup graph $\Gamma(G)$ introduced by Akbari et al. in [1]. The co-maximal subgroup graph $\Gamma(G)$ of a group G whose vertices are non-trivial proper subgroups of G and two vertices H and K are adjacent if $HK = G$. Though the definition allows the possibility of G to be infinite, in our discussion, we will focus mainly on finite groups. We discuss various graph parameters like diameter, connectedness, existence of isolated vertices, girth, bipartiteness etc. Finally, we will highlight some problems on realizability and graph isomorphisms, and some partial solutions to those questions in terms of properties of G . Most of the results presented in the lecture can be found in [1] and [2].

Basic edge-transitive oriented graphs of valency four

The talk is about finite connected 4-valent graphs admitting an edge-transitive and vertex-transitive subgroup G of automorphisms which preserves an orientation of the edges. But I will first talk about the general approach to describing families of graphs with strong symmetry properties using certain quotients.

A connected G -edge-transitive oriented 4-valent graph is basic if each quotient, modulo the orbits of a normal subgroup of G is degenerate: it is either a cycle (oriented or unoriented) or consists of a single vertex or a single edge. In other words, these are the graphs which are basic relative to normal quotient reduction. I will discuss the structure of these basic graphs using both group theoretic and combinatorial information. There are three kinds of basic examples: quasiprimitive, bi-quasiprimitive, and cyclic types. Apart from six infinite families of well-understood examples, the group G has a unique minimal normal subgroup $N = T^k$, for some simple group T , and the integer k is bounded: $k \in \{1, 2\}$ for quasiprimitive type; $k \in \{1, 2, 4, 8\}$ for bi-quasiprimitive type; and k is bounded above by certain explicit functions of r for cycle type, where the quotient modulo the N -orbits is a cycle of length r . All the bounds are tight, and in all cases we have constructed infinite families of examples meeting the bounds.

Perhaps the most startling case is where the quotient mod N is an unoriented cycle C of length r , and $N = T^k$ with T a nonabelian simple group. In this case our bound is $k \leq r2^r$. Here we have given examples meeting the bound only for $r = 3$, hence $k = 24$, and for any simple group T which can be generated by elements a, b of orders 2 and 3, respectively.

Collaborators. The work on the quasiprimitive case is joint with Jehan Al-bar, Ahman Al-kenani, Najat Muthana, and Pablo Spiga, published in 2016 and 2017. The other cases are a collaboration with Nemanja Poznanovic; the bi-quasiprimitive type has just been published in Algebraic Combinatorics, while the results for cycle type will first appear in Nem's thesis from the University of Melbourne.

This talk is intended to be accessible to beginning graduate students / students with a bachelor's degree in Mathematics.

CRG on Movement and Symmetry in Graphs Distinguished Lecture Series

Walter Carballosa Torres (Florida International University)
Hyperbolicity of some product of graphs

Nov 17, 2021

In this talk I will present a study on the Gromov's hyperbolicity of some product of graphs. The presentation is based on joint works that studied hyperbolicity of the lexicographic product, tensor product and graph join of two graphs, respectively. Product of graphs is a topic that has widely been study due to its applications in networks and regular structures. We characterize the hyperbolicity of these products

Lexicographic product: the lexicographic product graph $G_1 \circ G_2$ is hyperbolic if and only if G_1 is (unless if G_1 is trivial). In particular, we obtain the sharp inequalities $\delta(G_1) \leq \delta(G_1 \circ G_2) \leq \delta(G_1) + 3/2$, if G_1 is not a trivial graph, and we prove that second inequality is attained only if G_1 is a tree.

Tensor product: the tensor product graph $G_1 \times G_2$ is hyperbolic, then one factor is bounded and the other is hyperbolic. Besides, we prove that this necessary condition is also sufficient in many cases. In other cases, we find (not so simple) characterizations of hyperbolic tensor products.

Graph join: the graph join $G_1 + G_2$ is always hyperbolic since it's bounded. Moreover, we prove that for every two graphs G_1 and G_2 the hyperbolicity constant of its graph join $\delta(G_1 + G_2)$ belongs to $\{0, \frac{3}{4}, 1, \frac{5}{4}, \frac{3}{2}\}$ characterizing them in each case. Furthermore, we obtain sharp bounds, and even formulas in many cases, for the hyperbolicity constant.

On a generalization of the Erdős-Ko-Rado theorem to intersecting and set-wise intersecting perfect matchings

A perfect matching (\mathcal{PM}) in the complete graph K_{2k} is a set of edges by which every vertex is covered exactly once. Two \mathcal{PM} s are said to be t -intersecting if they have at least t edges in common. Another type of intersection that we can define on \mathcal{PM} s is set-wise intersection. Two \mathcal{PM} s P and Q of a graph on $2k$ vertices are said to be set-wise t -intersecting if there exist edges P_1, \dots, P_t in P and Q_1, \dots, Q_t in Q such that the union of edges P_1, \dots, P_t has the same set of vertices as the union of Q_1, \dots, Q_t . In this talk we show an extension of the famous Erdős-Ko-Rado theorem to intersecting and set-wise intersecting \mathcal{PM} for $t = 2$ and $t = 3$.

Soffía Árnadóttir (University of Waterloo)
University of Waterloo

Dec 1, 2021

Consider a group G acting transitively on the vertices of an infinite, cubic (3-regular) graph Γ such that the vertex stabilizers are infinite. We will see that if G is also edge-transitive on Γ , then Γ is the infinite cubic tree, and if not, then G has precisely two orbits on the edges. I will then focus on the latter case, with the added assumption that the graph has exactly two ends.

The talk is based on joint work with Waltraud Lederle and Rögnvaldur Möller, <https://arxiv.org/abs/2101.04064>.

Irregularities of Dirichlet L -functions and a Chebyshev-type bias for zeros

We describe a thin family of Dirichlet L -functions which have an irregular and perhaps unexpected behavior in their value distribution. This behavior has an arithmetic explanation and corresponds to the nonvanishing of a certain Gauss type sum. We give a complete classification of the characters for which these sums are nonzero and count the number of corresponding characters. It turns out that this Gauss type sum vanishes for 100% of primitive Dirichlet characters but there is an infinite (but zero density) subfamily of characters where the sum is nonzero.

Experimentally, this thin family of L -functions seems to have a significant and previously undetected bias in distribution of gaps between their zeros. After uncovering this bias, we re-examined the gaps between the zeros of the Riemann zeta-function and discovered an even more surprising phenomenon. If we list the gaps in increasing order and sum over arithmetic progressions of gaps, there seems to be a “Chebyshev-type” bias in the corresponding measures; the sum over certain arithmetic progressions of gaps are much larger than others! These observations seem to go well beyond the Random Matrix Theory model of L -functions.

This is joint work with Jonathan Bober and Zhenchao Ge.

Quanli Shen (Math and CS, U of Lethbridge)

Feb 1, 2021

The first moment of quadratic twists of modular L -functions

We obtain the asymptotic formula with an error term $O(X^{\frac{1}{2}+\varepsilon})$ for the smoothed first moment of quadratic twists of modular L -functions. The argument is largely based on a recursive method of Young (Acta Arith. 138(1):73–99, 2009 and Sel. Math. (N.S.) 19(2):509–543, 2013).

Dave Morris (Math and CS, U of Lethbridge)

Feb 8, 2021

Quasi-isometric bounded generation

A subset X *boundedly generates* a group G if every element g of G is the product of a bounded number of elements of X . This is a very powerful notion in abstract group theory, but geometric group theorists (and others) may also need a good bound on the norms of the elements of X that are used. (We do not want to have to use large elements of X to represent a small element of G .) In 1993, Lubotzky, Mozes, and Raghunathan proved an excellent result of this type for the case where G is the group $SL(n, \mathbb{Z})$ of n -by- n matrices with integer entries and determinant one, and X consists of the elements of the natural copies of $SL(2, \mathbb{Z})$ in G . We will explain the proof of this result, and discuss a generalization to other arithmetic groups.

David Nguyen (University of California, Santa Barbara)

Feb 22, 2021

Distribution of the ternary divisor function in arithmetic progressions

The ternary divisor function, denoted $\tau_3(n)$, counts the number of ways to write a natural number n as an ordered product of three positive integers. Thus, $\sum_{n=1}^{\infty} \tau_3(n)n^{-s} = \zeta^3(s)$. Given two coprime positive integers a and q , we study the distribution of τ_3 in arithmetic progressions $n \equiv a \pmod{q}$. The distribution of τ_3 in arithmetic progressions has a rich history and has applications to the distribution of prime numbers and moments of Dirichlet L -functions. We show that τ_3 is equidistributed on average for moduli q up to $X^{2/3}$, extending the individual estimate of Friedlander and Iwaniec (1985). We will also discuss an averaged variance of τ_3 in arithmetic progressions related to a recent conjecture of Rodgers and Soundararajan (2018) about asymptotic of this variance. One of the key inputs to this asymptotic come from a modified additive correlation sum of τ_3 .

Andrew Fiori (Math and CS, U of Lethbridge)

Mar 1, 2021

Unbounded Denominators for Non-Congruence Forms of Index 7

In this talk I will report on some recent joint work with Cameron Franc (McMaster) where we investigate the structure of modular forms for the non-congruence groups of minimal index. In contrast to the case of congruence groups, little is known about the Fourier coefficients of even the Eisenstein series let alone more general forms. One way in which non-congruence forms differ from congruence forms is that when their Fourier coefficients are algebraic the denominators are conjectured to diverge to infinity. We will demonstrate that this conjecture holds for the index 7 subgroups of $\mathrm{PSL}_2(\mathbb{Z})$ while highlighting some questions which remain open about the coefficients of Eisenstein series.

Amir Akbary (Math and CS, U of Lethbridge)

Mar 8, 2021

Sums of triangular numbers and sums of squares

For non-negative integers a , b , and n , let $t(a, b; n)$ be the number of representations of n as a sum of triangular numbers with coefficients 1 and 3 (a of ones and b of threes) and let $r(a, b; n)$ be the number of representations of n as a sum of squares with coefficients 1 and 3 (a of ones and b of threes). It is known that for a and b satisfying $1 \leq a + 3b \leq 7$, we have

$$t(a, b; n) = \frac{2}{2 + \binom{a}{4} + ab} r(a, b; 8n + a + 3b)$$

and for a and b satisfying $a + 3b = 8$, we have

$$t(a, b; n) = \frac{2}{2 + \binom{a}{4} + ab} (r(a, b; 8n + a + 3b) - r(a, b; (8n + a + 3b)/4)).$$

Such identities are not known for $a + 3b > 8$. We report on our joint work with Zafer Selcuk Aygin (University of Calgary) in which, for general a and b with $a + b$ even, we prove asymptotic equivalence of formulas similar to the above, as $n \rightarrow \infty$. One of our main results extends a theorem of Bateman, Datskovsky, and Knopp where the case $b = 0$ and general a was considered. Our approach is different from Bateman-Datskovsky-Knopp's proof where the circle method and singular series were used. We achieve our results by explicitly computing the Eisenstein components of the generating functions of $t(a, b; n)$ and $r(a, b; n)$.

Junxian Li (Max Planck Institute, Germany)

Mar 15, 2021

Uniform Titchmarsh divisor problems

The Titchmarsh divisor problem asks for an asymptotic evaluation of the average of the divisor function evaluated at shifted primes. We will discuss how strong error terms that are uniform in the shift parameters could be obtained using spectral theory of automorphic forms. We will also discuss the automorphic analogue of the Titchmarsh divisor problem. This is a joint work with E. Assing and V. Blomer.

Amita Malik (American Institute of Mathematics, California)

Mar 22, 2021

Partitions into parts concerning a Chebotarev condition

In this talk, we discuss the asymptotic behavior of the number of ways to write a given positive integer as a sum of primes powers concerning a Chebotarev condition. In special cases, this reduces to the study of partitions into primes in arithmetic progressions. While this study for ordinary partitions goes back to Hardy and Ramanujan, partitions into primes were recently re-visited by Vaughan. Our error term is sharp and improves on previous known estimates in the special case of primes as parts of the partition. As an application, monotonicity of this partition function is established explicitly via an asymptotic formula in connection to a result of Bateman and Erdős.

Babak MirafTAB (Math and CS, U of Lethbridge)

Mar 29, 2021

Infinite cycles in graphs

It turns out that homology of finite graphs is trivial, however when it comes to infinite graphs, it gets interesting. The problem of defining cycles in infinite graphs has attracted so many researchers. Diestel and Kühn have proposed viewing a graph as 1-complex, and defining a topology on the point set of the graph together with its ends. In this setting, a circle in the graph is a homeomorph of the unit circle S^1 in this topological space. For locally finite graphs this setting appears to be natural, as many classical theorems on cycles in finite graphs extend to the infinite setting. In this talk, we discuss this approach in details and also define a new notion for Hamiltonicity of infinite graphs. Depending on time constraint, we address the Lovász conjecture for infinite groups.

Oct 5, 2020

Primes in short intervals: Heuristics and calculations

We formulate, using heuristic reasoning, precise conjectures for the range of the number of primes in intervals of length y around x , where $y \ll (\log x)^2$. In particular, we conjecture that the maximum grows surprisingly slowly as y ranges from $\log x$ to $(\log x)^2$. We will show that our conjectures are somewhat supported by available data, though not so well that there may not be room for some modification. This is joint work with Andrew Granville.

Elchin Hasanalizade (Math and CS, U of Lethbridge)

Oct 19, 2020

Distribution of the divisor function at consecutive integers

The purpose of this talk is to discuss the famous Erdős-Mirsky conjecture and problems on consecutive values of multiplicative functions that arise in connection with this conjecture. We'll show how the results of Goldston et al. can be used to sharpen Hildebrand's earlier result on a conjecture of Erdős on limit points of the sequence $d(n)/d(n+1)$. If time permits, we'll also discuss some open problems.

Kubra Benli (University of Georgia)

Oct 26, 2020

Prime power residues modulo p

Let p be a prime number. For each positive integer $k \geq 2$, it is widely believed that the smallest prime that is a k th power residue modulo p should be $O(p^\epsilon)$, for any $\epsilon > 0$. Elliott proved that such a prime is at most $p^{\frac{k-1}{4}+\epsilon}$, for each $\epsilon > 0$. In this talk we will discuss the distribution of prime k th power residues modulo p in the range $[1, p]$, with a more emphasis on the subrange $[1, p^{\frac{k-1}{4}+\epsilon}]$ for $\epsilon > 0$.

Iren Darijani (Math and CS, U of Lethbridge)

Nov 2, 2020

Colourings of G -designs

A G -decomposition of a graph H consists of a set V of vertices of H together with a set \mathcal{B} of subgraphs (called blocks) of H , each isomorphic to G , that partition the edge set of H . A G -design of order n is a G -decomposition of the complete graph K_n on n vertices. A complete graph is a simple graph in which every pair of distinct vertices is connected by a unique edge. A G -design is said to be k -colourable if its vertex set can be partitioned into k sets (called colour classes) such that no block is monochromatic. It is k -chromatic if it is k -colourable but is not $(k - 1)$ -colourable.

The block intersection graph of a G -design with block set \mathcal{B} is the graph with \mathcal{B} as its vertex set such that two vertices are adjacent if and only if their associated blocks are not disjoint. The chromatic index of a graph H is the least number of colours that enable each edge of H to be assigned a single colour such that adjacent edges never have the same colour.

In this talk we will first see some results on the chromatic index of block intersection graphs of Steiner triple systems. A Steiner triple system of order v is a K_3 -design of order n with $n = v$. We will then discuss some other results on k -colourings of e -star systems for all $k \geq 2$ and $e \geq 3$. An e -star is a complete bipartite graph $K_{1,e}$. An e -star system of order $n > 1$, is a G -design of order n when G is an e -star. Finally, we will see some other results on k -colourings of path systems for any $k \geq 2$. A path system is a G -design when G is a path.

Yash Totani (Math and CS, U of Lethbridge)

Nov 16, 2020

On the number of representations of an integer as a sum of k triangular numbers

The m th r -gonal number is defined by

$$p_r(m) = [(r - 2)m^2 - (r - 4)m]/2.$$

The problem of finding the number of representations of an integer as a sum of k r -gonal numbers is well studied, however a lot of interesting related questions are still unresolved. When $r = 4$, this problem converts to the classical problem of finding the number of representations of an integer as a sum of k squares.

In this talk, we discuss the case $r = 3$ where we study the number of representations of an integer by k triangular (3-gonal) numbers. Let $t_k(n)$ be the number of representations of a positive integer n as a sum of k triangular numbers. One of the oldest results in connection with triangular numbers is due to Gauss who proved that $t_3(n) \geq 1$ for any positive integer n . We discuss some new results in the theory by Atanasov et al. where they provide exact formulas for $t_{4k}(n)$, which are proved mysteriously. Here, we discuss a method, inspired by the work of Dr. Zafer Selcuk Aygin, which can be used to give a more concrete proof for the result mentioned above using the modular forms of even integral weight. We also obtain an extension of the above and provide formulas for $t_{4k+2}(n)$ using the theory of odd integral weight modular forms for $\Gamma_0(8)$.

Dave Morris (Math and CS, U of Lethbridge)

Automorphisms of direct products of some circulant graphs

The direct product of two graphs X and Y is denoted $X \times Y$. This is a natural construction, so any isomorphism from X to X' can be combined with any isomorphism from Y to Y' to obtain an isomorphism from $X \times Y$ to $X' \times Y'$. Therefore, the automorphism group $\text{Aut}(X \times Y)$ contains a copy of $(\text{Aut } X) \times (\text{Aut } Y)$. It is not known when this inclusion is an equality, even for the special case where $Y = K_2$ is a connected graph with only 2 vertices.

Recent work of B. Fernandez and A. Hujdurović solves this problem when X is a “circulant” graph with an odd number of vertices (and $Y = K_2$). We will present a short, elementary proof of this theorem.

The Correction Factors in Artin's Type Problems

In 1927, Emil Artin formulated a conjecture for the density $\delta(g)$ of primes for which a given integer g is a primitive root, i.e., $\langle g \bmod p \rangle = \mathbb{F}_p^\times$. Such prime p does not split completely in the splitting field of $x^q - g$, indicated by K_q , for all primes $q \mid p - 1$. For $g \neq -1$ and non-square, Artin conjectured

$$\delta(g) = \prod_p \left(1 - \frac{1}{[K_p : \mathbb{Q}]} \right).$$

In 1957, computations, carried by Derrick H. Lehmer and Emma Lehmer, revealed that for some g (for example $g = 5$) the conjectured density is quite different from the one computed. Artin provided a correction factor to handle this mismatch. In fact, the correction factor appears because of the “entanglement” between number fields $K_n = \prod_{p \mid n} K_p$ for n square-free when the square-free part of g is congruent to 1 modulo 4. In 1967, Hooley proved the modified Artin's conjecture under the assumption of the generalized Riemann hypothesis.

In this talk, we will present *the character sums* method formulated by Lenstra, Moree and Stevenhagen which gives us an effective way to find the correction factor and the Euler product of the density in Artin's conjecture and the cyclicity problem for Serre curves. We will observe that this method does not work in some Artin-like problems such as the Kummerian Titchmarsh divisor problem. At the end, we will indicate that how a modification of the character sums method may lead to the correction factor in such problems.

Regular Representations of Groups

A natural way to understand groups visually is by examining objects on which the group has a natural permutation action. In fact, this is often the way we first show groups to undergraduate students: introducing the cyclic and dihedral groups as the groups of symmetries of polygons, logos, or designs. For example, the dihedral group D_8 of order 8 is the group of symmetries of a square. However, there are some challenges with this particular example of visualisation, as many people struggle to understand how reflections and rotations interact as symmetries of a square.

Every group G admits a natural permutation action on the set of elements of G (in fact, two): acting by right- (or left-) multiplication. (The action by right-multiplication is given by $\{\tau_g : g \in G\}$, where $\tau_g(h) = hg$ for every $h \in G$.) This action is called the *right- (or left-) regular representation* of G . It is straightforward to observe that this action is regular (that is, for any two elements of the underlying set, there is precisely one group element that maps one to the other). If it is possible to find an object that can be labelled with the elements of G in such a way that the symmetries of the object are precisely the right-regular representation of G , then we call this object a *regular representation* of G .

A Cayley (di)graph $\text{Cay}(G, S)$ on the group G (with connection set $S \subset G$) is defined to have the set G as its vertices, with an arc from g to sg for every $s \in S$. It is straightforward to see that the right-regular representation of G is a subset of the automorphism group of this (di)graph. However, it is often not at all obvious whether or not $\text{Cay}(G, S)$ admits additional automorphisms. For example, $\text{Cay}(\mathbb{Z}_4, \{1, 3\})$ is a square, and therefore has D_8 rather than \mathbb{Z}_4 as its full automorphism group, so is not a regular representation of \mathbb{Z}_4 . Nonetheless, since a regular representation that is a (di)graph must always be a Cayley (di)graph, we study these to determine when regular representations of groups are possible.

I will present results about which groups admit graphs, digraphs, and oriented graphs as regular representations, and how common it is for an arbitrary Cayley digraph to be a regular representation.

Explicit results about primes in Chebotarev's density theorem

Let L/K be a Galois extension of number fields with Galois group G , and let $C \subset G$ be a conjugacy class. Attached to each unramified prime ideal \mathfrak{p} in \mathcal{O}_K is the Artin symbol $\sigma_{\mathfrak{p}}$, a conjugacy class in G . In 1922 Chebotarev established what is referred to his density theorem (CDT). It asserts that the number $\pi_C(x)$ of such primes with $\sigma_{\mathfrak{p}} = C$ and norm $N_{\mathfrak{p}} \leq x$ is asymptotically $\frac{|C|}{|G|} Li(x)$ as $x \rightarrow \infty$, where $Li(x)$ is the usual logarithmic integral. As such, CDT is a generalisation of both the prime number theorem and Dirichlet's theorem on primes in arithmetic progressions. In light of Linnik's result on the least prime in an arithmetic progression, one may ask for a bound for the least prime ideal whose Artin symbol equals C . In 1977 Lagarias and Odlyzko proved explicit versions of CDT and in 1979 Lagarias, Montgomery and Odlyzko gave bounds for the least prime ideal in the CDT. Since 2012 several unconditional explicit results of these theorems have appeared with contributions by Zaman, Zaman and Thorner, Ahn and Kwon, and Winckler. I will present several recent results we have proven with Das, Ng, and Wong.

Feb 3, 2020

On the eta quotients whose derivatives are also eta quotients

In classical q-series studies there are examples of eta quotients whose derivatives are also eta quotients. The most famous examples can be found in works of S. Ramanujan and N. Fine. In 2019, in a joint work with P. C. Toh, we have given 203 pairs of such eta quotients, which we believe to be the complete list (see "When is the derivative of an eta quotient another eta quotient?", J. Math. Anal. Appl. 480 (2019) 123366). Recently, D. Choi, B. Kim and S. Lim have given a complete list of such eta quotients with squarefree levels (see "Pairs of eta-quotients with dual weights and their applications", Adv. Math. 355 (2019) 106779). Their findings support the idea that our list is complete.

In this talk we introduce a beautiful interplay between eta quotients, their derivatives and Eisenstein series. Then we share our work in progress (joint with A. Akbary) in proving the completeness of our list beyond squarefree levels.

Feb 24, 2020

Cyclicity of CM Elliptic Curves Modulo p

Let E be a CM elliptic curve defined over \mathbb{Q} . In light of the Lang-Trotter conjecture, there is a question asking for an asymptotic formula for the number of primes $p \leq x$ for which the reduction modulo p of E is cyclic. This has been studied by Akbary, Cojocaru, Gupta, M.R. Murty, V.K. Murty, and Serre. In this talk, we will discuss their work and some variants of the question.

Nathan Ng (Math and CS, U of Lethbridge)

Mar 2, 2020

Moments of the Riemann zeta function and mean values of long Dirichlet polynomials

The $2k$ -th moments $I_k(T)$ of the Riemann zeta function have been studied extensively. In the late 90's, Keating-Snaith gave a conjecture for the size of $I_k(T)$. At the same time Conrey-Gonek connected $I_k(T)$ to mean values of long Dirichlet polynomials with divisor coefficients. Recently this has been further developed by Conrey-Keating in a series of 5 articles. I will discuss my work relating $I_3(T)$ to smooth shifted ternary additive divisor sums and also recent joint work with Alia Hamieh on mean values of long Dirichlet polynomials with higher divisor coefficients.

Nathan Ng (Math and CS, U of Lethbridge)

Mar 9, 2020

The size of prime number error terms

Montgomery made a conjecture for the size of the error term in the prime number theorem. Similarly, Gonek made a conjecture for the size of the error term for the summatory function of the Mobius function. I will discuss these conjectures and the connection to large deviations of infinite sums of identically distributed random variables. This is joint work with Amir Akbary and Majid Shahabi.

Daniel Fiorilli (University of Ottawa and University of Paris – Saclay)

May 20, 2020

On the distribution of the error term in Chebotarev's density theorem and applications

We will discuss both extreme and generic values of the error term in Chebotarev's density theorem. This will allow us to deduce applications on a conjecture of K. Murty on the least unramified prime ideal in a given Frobenius set as well as on asymptotic properties of Chebyshev's bias. This is joint work with Florent Jouve, and builds on ideas of Rubinstein-Sarnak, Ng, K. Murty, R. Murty, and others.

June 8, 2020

Explicit Improvements to the Burgess Bound

The standard estimate for the size of a (Dirichlet) character sum is the well-known Pólya-Vinogradov inequality. However, this inequality only uses the modulus of the character and does not consider the length of the sum. For a bound that does consider the length of the sum, we have a family of estimates known as the Burgess bound. Owing to the size of their effective ranges, the Burgess bound is sometimes considered a "better" estimate.

Despite this, in an explicit setting, some improvements to the Pólya-Vinogradov inequality end up yielding improvements to the Burgess bound. In this talk, we will look at two such results. One involves the leading constant for the Burgess bound for characters of prime modulus, while the other makes improvements to the effective range of the Burgess bound for odd quadratic characters. The second topic is joint work with Matteo Bordignon.

Ethan Lee (UNSW Canberra, Australia)

June 15, 2020

Goldbach's Conjecture and Square-free Numbers

We introduce the Goldbach conjecture and some heuristic evidence to support it. Goldbach's conjecture is hard, so we consider some relaxations of Goldbach's conjecture, which has led to theorems by Helfgott and Dudek. Then, I give an account of the results and the main method used in joint work with F. Francis (submitted), which builds upon Dudek's result. Finally, we observe some conjectures, which would build upon the aforementioned results from myself and F. Francis.

Asif Zaman (University of Toronto)

June 22, 2020

An effective Chebotarev density theorem for fibres

Let K/k be a Galois extension of number fields. The Chebotarev density theorem asserts that, as x tends to infinity, the primes of k with norm at most x equidistribute according to their splitting behaviour in K . How large must x be to actually observe this equidistribution? Pierce, Turnage-Butterbaugh, and Wood have made remarkable progress on this central question for certain families of number fields. Their results rely on two key ingredients: (1) the Artin conjecture is known for every field in the family and (2) there are few common intermediate field extensions within the family. Dependence on (1) was removed in recent joint work with Thorner.

I will discuss forthcoming work with Lemke Oliver and Thorner where we prove an unconditional result that allows both (1) and (2) to be bypassed in many cases of interest. For example, we prove that almost all degree n S_n -extensions have GRH-quality bounds on the ℓ -torsion subgroups of their class groups.

Shabnam Akhtari (University of Oregon)

June 29, 2020

How to count (cubic and quartic) binary forms

In order to study interesting arithmetic, algebraic, analytic and geometric properties of binary forms, we often need a way to order them. I will discuss some natural ways to order binary forms $F(x, y)$ with integer coefficients, especially those of degree 3 and 4. I will show some of my recent works as examples of the importance of understanding the invariant theory of integral binary forms in order to count these important arithmetic objects.

The prime number theorem for automorphic L -functions

We describe a theorem due to Jianya Liu and Yangbo Ye (Pure and Applied Mathematics Quarterly, Volume 3, Number 2, 481–497, 2007) concerning the prime number theorem for automorphic L -functions. We state the theorem and review the strategy of the proof in comparison with the classical prime number theorem. An important ingredient is a new version of Perron's formula that represents a sum of complex numbers as a contour integral plus some specific error terms.

Khoa Dang Nguyen (University of Calgary)

Oct 21, 2019

An analogue of Ruzsa's conjecture for polynomials over finite fields

In 1971, Ruzsa conjectured that if $f : \mathbb{N} \rightarrow \mathbb{Z}$ with $f(n+k) \equiv f(n) \pmod{k}$ for every $n, k \in \mathbb{N}$ and $f(n) = O(\theta^n)$ with $\theta < e$ then f is a polynomial. In this paper, we investigate the analogous problem for the ring of polynomials over a finite field. This is joint work with Jason Bell.

The fourth moment of quadratic Dirichlet L -functions

In this talk, I will talk about the fourth moment of quadratic Dirichlet L -functions. Under the generalized Riemann hypothesis, we showed an asymptotic formula for the fourth moment. Unconditionally, we established a precise lower bound.

Peng-Jie Wong (Math and CS, U of Lethbridge)

Nov 4, 2019

Primes in Short Intervals

Bertrand's postulate states that there is always a prime in the interval $[x, 2x]$ for any $x \geq 1$. Applying the prime number theorem, one may further show that there is approximately $\int_x^{2x} \frac{dt}{\log t}$ primes in $[x, 2x]$ for sufficiently large x . There is a more difficult question concerning the distribution of primes p in short intervals when $[x, 2x]$ is replaced by $[x, x+h]$ for some $h \leq x$ and p is required to be congruent to a modulo q for some $(a, q) = 1$. In this talk, we will discuss how short $[x, x+h]$ can be. If time allows, we will sketch a proof of the Bombieri-Vinogradov theorem in short intervals, which answers such a question.

Allysa Lumley (Centre de Recherches Mathématiques, Montréal)

Nov 18, 2019

Distribution of Values of L -functions over Function Fields

Let $q \equiv 1 \pmod{4}$ be a prime power and \mathbb{F}_q be the finite field with q elements. Let $1/2 < \sigma < 1$ be fixed. We consider D a monic square-free polynomial in $\mathbb{F}_q[T]$ and χ_D the Kronecker symbol associated with D . In this talk, we will discuss the distribution of large values of $\log L(\sigma, \chi_D)$ with D varying over monic square-free polynomials with degree $n \rightarrow \infty$. We will highlight the expected similarities to the situation over quadratic extensions of \mathbb{Q} as well as the surprising differences.

Po-Han Hsu (Louisiana State University)

Nov 25, 2019

Large deviation principle for the divisor function

Let $\omega(n)$ denote the number of distinct prime divisors of n . Let $W(m)$ be a random integer chosen uniformly from $\{n : n \leq m, n \in \mathbb{N}\}$. Let $X(m)$ be $\omega(W(m))$. The celebrated Erdős-Kac theorem asserts that

$$\frac{X(m) - \log \log m}{\sqrt{\log \log m}} \rightarrow N(0, 1),$$

where $N(0, 1)$ is the standard normal distribution.

In 2016, Mehrdad and Zhu studied the large and moderate deviations for the Erdős-Kac theorem. In this talk, we will give a brief introduction to the theory. Then we will discuss how to establish the large deviation principle for $X(m)/\log \log m$. If time allows, we will discuss some generalisations.

This is a joint work with Dr Peng-Jie Wong.

Andrew Fiori (Math and CS, U of Lethbridge)

Dec 2, 2019

Simplicity of ABV-packets for Arthur Type Parameters in GL_n

In this talk we will discuss a combinatorial approach to studying the geometry of the moduli space of Langlands parameters for GL_n . We will first discuss several connections between the study of partitions and the study of nilpotent conjugacy classes. We then generalize some of these ideas to describe a relationship between multi-segments and orbits in the moduli space of Langlands parameters. Finally we shall explain how these ideas lead to a proof that simple parameters have simple packets.

Jan 21, 2019

Ambiguous Solutions of a Pell Equation

It is known that if the negative Pell equation $X^2 - DY^2 = -1$ is solvable (in integers), and if (x, y) is its solution with smallest positive x and y , then all of its solutions (x_n, y_n) are given by the formula

$$x_n + y_n\sqrt{D} = \pm(x + y\sqrt{D})^{2n+1}$$

for $n \in \mathbb{Z}$. Furthermore, a theorem of Walker from 1967 states that if the equation $aX^2 - bY^2 = \pm 1$ is solvable, and if (x, y) is its solution with smallest positive x and y , then all of its solutions (x_n, y_n) are given by

$$x_n\sqrt{a} + y_n\sqrt{b} = \pm(x\sqrt{a} + y\sqrt{b})^{2n+1}$$

for $n \in \mathbb{Z}$. We describe a unifying theorem that includes both of these results as special cases. The key observation is a structural theorem for the non-trivial ambiguous classes of the solutions of Pell equations $X^2 - DY^2 = \pm N$. This talk is based on the work of Forrest Francis in an NSERC USRA project in summer 2015.

Hadi Kharaghani (Math and CS, U of Lethbridge)

Feb 4, 2019

Two new classes of Hadamard matrices

A Hadamard matrix H of order $4n^2$ is said to be *skew-regular* if it is of skew-type and the absolute values of the row sums are all $2n$.

It is conjectured that for each odd integer n there is a skew-regular matrix of order $4n^2$. A Hadamard matrix H of order m is said to be *balancedly splittable* if there is an $\ell \times m$ submatrix H_1 of H such that inner products for any two distinct column vectors of H_1 take at most two values.

It is conjectured that only (Sylvester) Hadamard matrices of order 4^n are balancedly splittable. The existence and applications of these two very interesting classes of matrices to Hadamard diagonalizable strongly regular graphs, maximal equiangular lines set, doubly regular tournament, and unbiased Hadamard matrices will be discussed in detail.

Nathan Ng (Math and CS, U of Lethbridge)
Discrete moments of the Riemann zeta function

Feb 11, 2019

In this talk I will consider the discrete moments

$$J_k(T) = \sum_{0 < \gamma < T} |\zeta'(\rho)|^{2k},$$

where $\zeta(s)$ is the Riemann zeta function, $\rho = \beta + i\gamma$ is a non-trivial zero of $\zeta(s)$, and $T > 0$. In the 1980's Steve Gonek and Dennis Hejhal (independently) studied these moments and proposed a conjecture for the size of $J_k(T)$. I will give a survey of the known results towards the Gonek-Hejhal conjecture on $J_k(T)$. If time permits, I will present several new results.

Jack Kllys (University of Calgary)
Cohen-Lenstra heuristics and counting number fields

Feb 25, 2019

We will discuss the Cohen-Lenstra heuristics, both in the classical and non-abelian setting. In particular we will make the connection between these heuristics and the problem of counting extensions of quadratic fields with fixed Galois groups, and when knowledge of the latter implies such heuristics. Finally we will discuss our recent work on the non-abelian case and counting unramified 2-group extensions of quadratic fields.

Joy Morris (Math and CS, U of Lethbridge)
Counting Digraphical Regular Representations (DRRs)

Mar 4, 2019

A *Digraphical Regular Representation* (DRR) for a group G is a directed graph whose full automorphism group is the regular representation of G . In 1981, Babai showed that with five small exceptions, there is at least one DRR for every finite group.

A *Cayley digraph* on a group G is a group that contains the regular representation of G in its automorphism group. So when a Cayley digraph is a DRR, its automorphism group is as small as possible given that constraint.

The question of whether or not requiring a certain level of symmetry (in this case, a Cayley digraph) makes having additional symmetry more likely is a natural one, particularly in light of results by Erdős and others proving that almost every graph is asymmetric.

In some 1981 and 1982 papers, Babai and Godsil conjectured that as $r \rightarrow \infty$, over all groups G of size r , the proportion of Cayley digraphs that are DRRs tends to 1. They proved this to be true for the restricted family of nilpotent groups of odd order.

I will talk about recent joint work with Pablo Spiga in which we prove this conjecture.

Peng-Jie Wong (Math and CS, U of Lethbridge)
On Siegel Zeros

Mar 11, 2019

Siegel zeros (or Landau-Siegel zeros) are potential counterexamples to the generalised Riemann hypothesis (for L -functions). Such zeros, if exist, have to be “very close” to 1 over the complex plane.

In this talk, we will discuss some results concerning Siegel zeros and their applications. If time permits, we will talk about the corresponding “Siegel-Walfisz theorems” for certain L -functions.

Lee Troupe (Math and CS, U of Lethbridge)

Mar 18, 2019

Sums of divisors

What happens when you add up the divisors of an integer? This seemingly innocuous question has motivated mathematicians across the ages, from antiquity to the present day. In this talk, we'll survey some conjectures and results on the functions $s(n)$, the sum of the proper divisors of an integer n , and $\sigma(n) = s(n) + n$, the sum of all divisors of n . The ancient Greeks derived religious significance from certain values of these functions; we'll do no such thing in this talk. However, by asking simple questions whose answers turn out to be very complicated – if they're known at all – we will see that an air of mystery continues to surround these two fascinating functions. **The first half of this talk, at the very least, will be extremely accessible to everyone;** tell your students!

Qing Zhang (University of Calgary)

Mar 25, 2019

On the holomorphy of adjoint L-function for $GL(3)$

L-functions associated with automorphic forms are vast generalizations of Riemann zeta functions and Dirichlet L-functions. Although the theory of L-functions play a fundamental role in number theory, it is still largely conjectural. If π is an irreducible cuspidal automorphic representation of GL_n over a number field F and $\tilde{\pi}$ is its dual representation, it is conjectured that the Dedekind zeta functions $\zeta_F(s)$ (which is the Riemann zeta function when $F = \mathbb{Q}$) “divides” the Rankin-Selberg L-function $L(s, \pi \times \tilde{\pi})$, i.e., the quotient $L(s, \pi \times \tilde{\pi})/\zeta_F(s)$ (which is called the adjoint L-function of π) should be entire. For $n = 2$, this conjecture was proved by Gelbart-Jacquet. In this talk, I will give a sketchy survey of constructions of some L-functions, including the Rankin-Selberg L-function $L(s, \pi_1 \times \pi_2)$, and report our recent work on the above conjecture when $n = 3$. This is a joint work with Joseph Hundley.

Quanli Shen (Math and CS, U of Lethbridge)

Apr 1, 2019

The ternary Goldbach problem with primes in positive density sets

The ternary Goldbach problem stated that every odd integer greater than 5 can be written as sums of three primes. This was proved by Vinogradov for all sufficiently large odd integers and completely proved by Helfgott. On the other hand, by using Green's transference principle method one can extend Vinogradov's result to a density version. In this talk, I will talk about recent results in this direction.

Majid Shahabi

The appearance of p-adic numbers

In this talk, we present an introduction to p-adic numbers and their appearance in number theory. In particular, we give a proof of Ostrowski's theorem.

Cameron Franc (University of Saskatchewan)

Jun 24, 2019

Classification of some three-dimensional vertex operator algebras

Vertex operator algebras (VOAs) as discussed in this talk are graded complex vector spaces with a collection of many bilinear operations satisfying some intricate identities. They first arose in mathematics and physics via the study of string theory and conformal field theories, in the study of the Monster group and moonshine, and in the study of the representation theory of affine Lie algebras. From their inception it has been known that VOAs are deeply connected with the theory of modular forms.

In this talk we will explain how results on vector valued modular forms can be used to classify VOAs satisfying certain finiteness conditions. Our classification for VOAs with exactly three simple representations rests on using arithmetic properties of a family of modular forms expressed in terms of generalized hypergeometric series. The classification of the integral specializations of this family relies on properties of the monodromy, and on results on distributions of primes in arithmetic progressions. No prior familiarity with VOAs will be assumed, and we will focus primarily on the number theoretic aspects of the problem.

Fall 2018

Allysa Lumley (York University, Ontario)

Aug 27, 2018

Distribution of Values of L -functions associated to Hyperelliptic Curves over Finite Fields

In 1992, Hoffstein and Rosen proved a function field analogue to Gauß' conjecture (proven by Siegel) regarding the class number, h_D , of a discriminant D by averaging over all polynomials with a fixed degree. In this case $h_D = |\text{Pic}(\mathcal{O}_D)|$, where $\text{Pic}(\mathcal{O}_D)$ is the Picard group of \mathcal{O}_D . Andrade later considered the average value of h_D , where D is monic, squarefree and its degree $2g + 1$ varies. He achieved these results by calculating the first moment of $L(1, \chi_D)$ in combination with Artin's formula relating $L(1, \chi_D)$ and h_D . Later, Jung averaged $L(1, \chi_D)$ over monic, squarefree polynomials with degree $2g + 2$ varying. Making use of the second case of Artin's formula he gives results about $h_D R_D$, where R_D is the regulator of \mathcal{O}_D .

For this talk we discuss the complex moments of $L(1, \chi_D)$, with D monic, squarefree and degree n varying. Using this information we can describe the distribution of values of $L(1, \chi_D)$ and after specializing to $n = 2g + 1$ we give results about h_D and specializing to $n = 2g + 2$ we give results about $h_D R_D$.

Open problem session

Transversal This, Transversal That

We will discuss several results related to transversals in Latin squares (think "Sudoku") and other Latin square-like objects. These results centre around showing the existence of, the number of, or the structure of transversals in different cases. Several patterns have been unearthed via computation that will also be discussed. These patterns are often related to the permanent of certain 0-1 matrices that can be used to count the number of transversals in Latin squares.

Mean values of L -functions

In the past twenty years there has been a flurry of activity in the study of mean values of L -functions. This was precipitated by groundbreaking work of Keating and Snaith in which they modelled these mean values by random matrix theory. In this talk I will survey the best known asymptotic results for the mean values of L -functions in certain families (the Riemann zeta function on the half line and/or quadratic Dirichlet L -functions at the central point $s = 1/2$).

Lee Troupe (Math and CS, U of Lethbridge)

Distributions of polynomials of additive functions

How is the set of values of an arithmetic function distributed? In a seminal 1940 paper, Erdős and Kac answered this question for a class of additive functions satisfying certain mild hypotheses, a class which includes the number-of-prime-divisors function. Using ideas from both probability and number theory, they showed that the values of these additive functions tend toward a Gaussian normal distribution. In the intervening years, this “Erdős–Kac class” of additive functions has been broadened to include certain compositions of arithmetic functions, as well as arithmetic functions defined on natural sequences of integers, such as shifted primes and values of polynomials. In this talk, we will discuss recent joint work with Greg Martin (UBC) which further expands the Erdős–Kac class to include arbitrary sums and products of additive functions (satisfying the same mild hypotheses).

Linear recurrence sequences and some related results in arithmetic dynamics and ergodic theory

First we introduce some results about certain simple diophantine equations involving linear recurrence sequences. Then we present 2 applications. The first application involves the so-called Orbit Intersection Problem for the arithmetic dynamics of semiabelian varieties and linear spaces. The second application involves certain ergodic averages for surjective endomorphisms of compact abelian groups. Parts of this come from joint work with Dragos Ghioca.

Oct 15, 2018

Fractional clique k -covers, vertex colorings and perfect graphs

The relationship between independence number, chromatic number, clique number, clique cover number and their fractional analogues is well-established for perfect graphs. Here, we study the clique k -cover number $cc_k(G)$ and the fractional clique k -cover number $cc_{fk}(G)$ of a graph G . We relate $cc_{fk}(G)$ to the fractional chromatic number of the complement \overline{G} , obtaining a Nordhaus–Gaddum type result. We modify the method of Kahn and Seymour, used in the proof of the fractional Erdős–Faber–Lovász conjecture, to derive an upper bound on $cc_{fk}(G)$ in terms of the independence number $\alpha(G')$ of a particular induced subgraph G' of G . When G is perfect, we get the sharper relation $cc_{fk}(G) = kcc_1(G) = k\alpha(G) \leq cc_k(G)$. This is in line with a result of Grötschel, Lovász, and Schrijver on clique covers of perfect graphs. Moreover, we derive an upper bound on the fractional chromatic number of any graph, which is tight for infinitely many perfect as well as non-perfect graphs. This is joint work with Daya Gaur (Lethbridge).

The Least Prime in the Chebotarev Density Theorem

The classic theorem of Chebotarev tells us that for any Galois extension L/K of degree n the proportion of primes of K , whose Frobenius conjugacy class is a given conjugacy class of the Galois group is proportional to the size of that conjugacy class. If one interprets this as a statement that the Frobenius of a randomly chosen prime is uniformly distributed, then a natural consequence is that if we begin selecting primes at random, by the time we select roughly $n \log(n)$ primes, we should expect to encounter every conjugacy class at least once. Given that selecting the first m primes is hardly random, and there are infinitely many fields it is hardly surprising that this expectation will often not be met by simply looking at the first m unramified degree one primes.

None the less, there are many known and conjectured upper bounds, relative to the absolute discriminant of L , on the smallest prime for the Chebotarev theorem.

In this talk we will discuss several aspects of this problem, including, as time allows, some recent work on computationally verifying some of these conjectures for all fields with small discriminants and on the discovery, by way of this computational verification, of an infinitely family of fields for which the smallest prime in the Chebotarev theorem is “large”.

Dave Morris (Math and CS, U of Lethbridge)

Oct 29, 2018

Cayley graphs of order kp are hamiltonian for $k < 48$

For every generating set S of any finite group G , there is a corresponding Cayley graph $\text{Cay}(G; S)$. It was conjectured in the early 1970's that $\text{Cay}(G; S)$ always has a hamiltonian cycle, but there has been very little progress on this problem. Joint work with Kirsten Wilk has established the conjecture in the special case where the order of G is kp , with $k < 48$ and p prime. This was not previously known for values of k in the set $\{24, 32, 36, 40, 42, 45\}$.

Nov 5, 2018

Dirichlet's Theorem for Modular Forms

Dirichlet's theorem on arithmetic progressions states that for any $(a, q) = 1$, there are infinitely many primes congruent to a modulo q . Such a theorem together with Euler's earlier work on the infinitude of primes represents the beginning of the study of L-functions and their connection with the distribution of primes.

In this talk, we will discuss some ingredients of the proof for the theorem. Also, we will explain how such an L-function approach leads to Dirichlet's theorem for modular forms that gives a count of Fourier coefficients of modular forms over primes in arithmetic progressions.

Kirsty Chalker (Math and CS, U of Lethbridge)

Nov 19, 2018

Perron's formula and explicit bounds on sums

Previously, in this seminar series, we have heard about explicit bounds on

$$\psi(x) := \sum_{n \leq x} \Lambda(n),$$

which refers to the von Mangoldt function $\Lambda(n)$. The point of lift-off for bounding this sum is the explicit formula, which pulls the zeros of the Riemann zeta-function into the equation. However, there are other sums for which using an explicit formula is currently unconditionally impossible. In this talk, I will outline the work of my current thesis, in which I prove bounds for a somewhat general function $\sum_{n \leq x} \frac{a_n}{n^s}$ with $a_n, s \in \mathbb{C}$, and apply these bounds to the sums

$$M(x) := \sum_{n \leq x} \mu(n) \quad \text{and} \quad m(x) = \sum_{n \leq x} \frac{\mu(n)}{n},$$

which refer to the Möbius function $\mu(n)$.

Farzad Maghsoudi (Math and CS, U of Lethbridge)

Nov 26, 2018

Finding Hamiltonian cycles in Cayley graphs of order $6pq$

Suppose G is a finite group of order $6pq$ such that p and q are distinct prime numbers. It is conjectured that, if S is any generating set of G , then there is a Hamiltonian cycle in $\text{Cay}(G; S)$. The talk will discuss a special case of this problem which is solved.

Lucile Devin (University of Ottawa, Ontario)

Dec 3, 2018

Continuity of the limiting logarithmic distribution in Chebyshev's bias

Following the framework of Rubinstein and Sarnak for Chebyshev's bias, one obtains a limiting logarithmic distribution μ . Then assuming that the zeros of the L -functions are linearly independent over \mathbf{Q} , one can show that the distribution μ is smooth.

Inspired by the notion of self-sufficient zeros introduced by Martin and Ng, we use a much weaker hypothesis of linear independence to show that the distribution μ is continuous. In particular the existence of one self-sufficient zero is enough to ensure that the bias is well defined.

Jan 29, 2018

Mean values of long Dirichlet polynomials

A Dirichlet polynomial is a function of the form

$$A(t) = \sum_{n \leq N} a_n n^{-it}$$

where a_n is a complex sequence, $N \in \mathbb{N}$, and $t \in \mathbb{R}$. For $T \geq 1$, the mean values

$$\int_0^T |A(t)|^2 dt$$

play an important role in the theory of L-functions. I will discuss work of Goldston and Gonek on how to evaluate these integrals in the case that $T < N < T^2$. This will depend on the correlation sums

$$\sum_{n \leq x} a_n a_{n+h} \text{ for } h \in \mathbb{N}.$$

If time permits, I will discuss a conjecture of Conrey and Keating in the case that a_n corresponds to a generalized divisor function and $N > T$.

Ha Tran (University of Calgary)

Feb 12, 2018

Reduced Ideals from the Reduction Algorithm

Reduced ideals of a number field F have inverses of small norms and they form a finite and regularly distributed set in the infrastructure of F . Therefore, they can be used to compute the regulator and the class number of a number field [5, 3, 2, 1, 4]. One usually applies the reduction algorithm (see Algorithm 10.3 in [4]) to find them. Ideals obtained from this algorithm are called 1-reduced. There exist reduced ideals that are not 1-reduced. We will show that these ideals have inverses of larger norms among reduced ones. Especially, we represent a sufficient and necessary condition for reduced ideals of real quadratic fields to be obtained from the reduction algorithm.

A Geometric Description of Arthur Packets

In this talk I will discuss joint work with Clifton Cunningham, Ahamed Moussaoui, James Mracek and Bin Xu.

I will begin by giving a brief overview of the (conjectural) Langlands Correspondence, focusing in particular on Vogan’s geometric reformulation of the local Langlands Correspondence. We will then discuss some geometric objects that arise as part of several conjectures which give geometric interpretations to Arthur packets and their associated stable distributions under the LLC. More specifically we shall discuss equivariant perverse sheaves and their vanishing cycles.

Mar 5, 2018

On the size of the gcd of $a^n - 1$ and $b^n - 1$

We review some results, from the last twenty years, on the problem of bounding

$$\gcd(a^n - 1, b^n - 1),$$

as n varies. Here either a and b are integers or a and b are polynomials with coefficients in certain fields. In spite of elementary nature of the problem, the results are depended on tools from Diophantine approximation and Diophantine geometry.

Steve Wilson (Northern Arizona University)

Mar 12, 2018

The BGCG Construction

Well, it's not really a construction yet — it's more like a template for constructions. It's a way to take many copies of one tetravalent graph B , the 'base graph', and identify each edge-midpoint with one other according to another graph C , the 'connection graph' to produce a bipartite tetravalent graph. If the identifying is done with caution, wisdom and, um, insouciance, the resulting graph will have lots of symmetry.

The cunning of the identifications is related to edge-colorings of the base graph which are themselves nicely symmetric, and we will give several examples where the symmetry can actually be achieved.

Mar 19, 2018

On Generalisations of the Titchmarsh divisor problem

The study of the asymptotic behaviour of the summatory function of the number of divisors of shifted primes was initiated by Titchmarsh, who showed that under the generalised Riemann hypothesis, one has

$$\sum_{p \leq x} \tau(p - a) = x \prod_{p \nmid a} \left(1 + \frac{1}{p(p-1)}\right) \prod_{p|a} \left(1 - \frac{1}{p}\right) + O\left(\frac{x \log \log x}{\log x}\right),$$

where τ denotes the divisor function. The above formula was first proved unconditionally by Linnik via the dispersion method. Moreover, applying the celebrated Bombieri-Vinogradov theorem, Halberstam and Rodriguez independently gave another proof.

In this talk, we shall study the Titchmarsh divisor problem in arithmetic progressions by considering the sum

$$\sum_{\substack{p \leq x \\ p \equiv b \pmod{r}}} \tau(p - a).$$

Also, we will try to explain how to obtain an asymptotic formula for the same, uniform in a certain range of the modulus r . If time allows, we will discuss a number field analogue of this problem by considering the above sum over primes satisfying Chebotarev conditions.

Cayley index and Most Rigid Representations (MRRs)

For any finite group G , a natural question to ask is the order of the smallest possible automorphism group for a Cayley graph on G . A particular Cayley graph whose automorphism group has this order is referred to as an MRR (Most Rigid Representation), and its *Cayley index* is the index of the regular representation of G in its automorphism group. Study of GRRs (Graphical Regular Representations, where the full automorphism group is the regular representation of G) showed that with the exception of two infinite families and ten individual groups, every group admits a Cayley graph whose MRRs are GRRs, so that the Cayley index is 1. I will present results that complete the determination of the Cayley index for those groups whose Cayley index is greater than 1. This is based on joint work with Josh Tymnurski, who was an undergraduate student here at the time.

Values of arithmetic functions at consecutive arguments

We shall place in a general context the following result recently (*) obtained jointly with Yuri Bilu (Bordeaux), Sanoli Gun (Chennai) and Florian Luca (Johannesburg).

Theorem. *Let $\tau(\cdot)$ be the classical Ramanujan τ -function and let k be a positive integer such that $\tau(n) \neq 0$ for $1 \leq n \leq k/2$. (This is known to be true for $k < 10^{23}$, and, conjecturally, for all k .) Further, let σ be a permutation of the set $\{1, \dots, k\}$. We show that there exist infinitely many positive integers m such that*

$$|\tau(m + \sigma(1))| < |\tau(m + \sigma(2))| < \dots < |\tau(m + \sigma(k))|.$$

The proof uses sieve method, Sato-Tate conjecture, recurrence relations for the values of τ at prime power values.

(*) Hopefully to appear in 2018.

Alia Hamieh (University of Northern British Columbia)

May 7, 2018

Non-vanishing of L -functions of Hilbert Modular Forms inside the Critical Strip

In this talk, I will discuss recent joint work with Wissam Raji. We show that, on average, the L -functions of cuspidal Hilbert modular forms with sufficiently large weight k do not vanish on the line segments $\Im(s) = t_0$, $\Re(s) \in (\frac{k-1}{2}, \frac{k}{2} - \epsilon) \cup (\frac{k}{2} + \epsilon, \frac{k+1}{2})$. The proof follows from computing the Fourier expansion of a certain kernel function associated with Hilbert modular forms and estimating its first Fourier coefficient. This result is analogous to the case of classical modular forms which was proved by W. Kohnen in 1997.

Nearly supersolvable groups and Artin's conjecture

Let K/k be a Galois extension of number fields with Galois group G , and let ρ be a non-trivial irreducible representation of G of dimension n . The Artin holomorphy conjecture asserts that the Artin L -function attached to ρ extends to an entire function.

It is well-known that when $n = 1$, this conjecture follows from Artin reciprocity. Also, by the works of Langlands and many others, we know that this conjecture is valid for $n = 2$ under certain conditions. However, in general, the Artin holomorphy conjecture is wildly open.

In this talk, we will discuss how elementary group theory plays a role in studying the Artin holomorphy conjecture and introduce the notion of “nearly supersolvable groups”. If time allows, we will explain how such groups lead to a proof of the Artin holomorphy conjecture for Galois extensions of degree less than 60.

Muhammad Khan (Math and CS, U of Lethbridge)

Sept 25, 2017

The contact graphs of totally separable packings

Contact graphs have emerged as an important tool in the study of translative packings of convex bodies and have found numerous applications in materials science. The contact number of a packing of translates of a convex body is the number of edges in the contact graph of the packing, while the Hadwiger number of a convex body is the maximum vertex degree over all such contact graphs. In this talk, we investigate the Hadwiger and contact numbers of totally separable packings of convex bodies, known as the separable Hadwiger number and the separable contact number, respectively. We show that the separable Hadwiger number of any smooth strictly convex body in dimensions $d = 2, 3, 4$ is $2d$ and the maximum separable contact number of any packing of n translates of a smooth strictly convex domain is $\lfloor 2n - 2\sqrt{n} \rfloor$. Our proofs employ a characterization of total separability in terms of hemispherical caps on the boundary of a smooth convex body, Auerbach bases of finite dimensional real normed spaces, angle measures in real normed planes, minimal perimeter polyominoes and an approximation of smooth σ -symmetric strictly convex domains by, what we call, Auerbach domains. This is joint work with K. Bezdek (Calgary) and M. Oliwa (Calgary).

Andrew Fiori (Math and CS, U of Lethbridge)

Oct 2, 2017

The average number of quadratic Frobenius pseudoprimes

Primality testing has a number of important applications. In particular in cryptographic applications the complexity of existing deterministic algorithms causes increasing latency as the size of numbers we must test grow and the number of tests we must run before finding a prime grows aswell. These observations lead one to consider potentially non-deterministic algorithms which are faster, and consequently leads one to consider the false positives these algorithms yield, which we call pseudoprimes.

In this talk I will discuss my recent work with Andrew Shallue where we study Quadratic Frobenius Pseudoprimes. I shall describe our results on an asymptotic lower bounds on the number of false positives. These results represent a generalization of those Erdős-Pomerance concerning similar problems for (Fermat) pseudoprimes.

Lee Troupe (University of British Columbia)

Oct 16, 2017

Normally distributed arithmetic functions

In the late 1930s, Paul Erdős attended a seminar at Cornell University given by Mark Kac, who suspected that divisibility by primes satisfies a certain “statistical independence” condition. If this were true, the central limit theorem could be used to show that the number of distinct prime factors of n , as n varies over the natural numbers, is normally distributed, with mean $\log \log n$ and standard deviation $\sqrt{\log \log n}$. Erdős used sieve methods to confirm Kac’s intuition, and the resulting Erdős-Kac theorem is a foundational result in the field of probabilistic number theory. Many different proofs of and variations on the Erdős-Kac theorem have been given in the intervening decades. This talk will highlight some of these results and the techniques used to obtain them, including recent work of the speaker and Greg Martin (UBC).

Sam Broadbent, Habiba Kadiri, and Kirsten Wilk (Math and CS, U of L) Oct 23, 2017

Sharper bounds for Chebyshev functions $\theta(x)$ and $\psi(x)$

In this talk we report on some research projects from summer 2017 supported by NSERC-USRA. In the first part of the project, we surveyed all existing explicit results from the past 60 years on prime counting functions, with a special focus on $\theta(x)$ (counting $\log p$ for each prime $p \leq x$). In the second part, we provided new bounds for the Chebyshev function $\psi(x)$ based on a recent zero density result for the zeros of the Riemann zeta function (due to Kadiri-Lumley-Ng). Finally, we have established the current best results for the prime counting function $\theta(x)$ for various ranges of x .

Akshaa Vatwani (University of Waterloo, Ontario)

Oct 30, 2017

Variants of equidistribution in arithmetic progression

It is well known that the prime numbers are equidistributed in arithmetic progression. Such a phenomenon is also observed more generally for a class of multiplicative functions. We derive some variants of such results and give an application to tuples of squarefree integers in arithmetic progression. We also discuss an interesting application that relates to the Chowla conjecture on correlations of the Möbius function, and show its relevance to the twin prime conjecture.

Károly Bezdek (University of Calgary)

Nov 6, 2017

Bounds for totally separable translative packings in the plane

A packing of translates of a convex domain in the Euclidean plane is said to be totally separable if any two packing elements can be separated by a line disjoint from the interior of every packing element. This notion was introduced by G. Fejes Toth and L. Fejes Toth (1973) and has attracted significant attention. In this lecture I will discuss the separable analogue of the classical inequality of N. Oler (from geometry of numbers) for totally separable translative packings of convex domains and then derive from it some new results. This includes finding the largest density of totally separable translative packings of an arbitrary convex domain and finding the smallest area convex hull of totally separable packings (resp., totally separable soft packings) generated by given number of translates of a convex domain (resp., soft convex domain). Last but not least, we determine the largest covering ratio (that is, the largest fraction of the plane covered) of totally separable soft circle packings with given soft parameter. This is a joint work with Zsolt Langi (Univ. of Technology, Budapest, Hungary).

Forrest Francis (Math and CS, U of Lethbridge)

Nov 20, 2017

Euler's function on products of primes in progressions

Let $\phi(n)$ be Euler's totient function and let q and a be fixed coprime natural numbers. Denote by $S_{q,a}$ the set of natural numbers whose prime divisors are all congruent to a modulo q . We can establish

$$\limsup_{n \in S_{q,a}} \frac{n}{\phi(n)(\log(\phi(q)\log n))^{1/\phi(q)}} = \frac{1}{C(q,a)},$$

where $C(q,a)$ is a constant associated with a theorem of Mertens. We may then wish to know whether there are infinitely many n in $S_{q,a}$ for which

$$(*) \quad \frac{n}{\phi(n)(\log \phi(q)\log n)^{1/\phi(q)}} > \frac{1}{C(q,a)}$$

is true. In the case $q = a = 1$, Nicolas (1983) established that if the Riemann hypothesis is true, then $(*)$ holds for all primorials (products of the form $\prod_{p \leq x} p$), but if the Riemann hypothesis is false then there are infinitely many primorials for which $(*)$ is true and infinitely many primorials for which $(*)$ is false.

In this talk we will show that, for some $q > 1$, the work of Nicolas can be generalized by replacing the Riemann hypothesis with analogous conjectures for Dirichlet L -functions and replacing the primorials with products of the form

$$\prod_{\substack{p \leq x \\ p \equiv a \pmod{q}}} p.$$

Sara Sasani (Math and CS, U of Lethbridge)

Nov 27, 2017

A strongly regular decomposition of the complete graph and its association scheme

A *Strongly Regular Graph*, $\text{SRG}(\nu, k, \lambda, \mu)$, is a k -regular graph with ν vertices such that every two adjacent vertices have λ common neighbors, and every two non-adjacent vertices have μ common neighbors. For each positive integer m , a construction for 2^m disjoint $\text{SRG}(2^{2m}(2^m + 2), 2^{2m} + 2^m, 2^m, 2^m)$ will be shown to form a decomposition of the complete graph with $2^{2m}(2^m + 2)$ vertices, if the cliques of size 2^{2m} is considered as a strongly regular graph with parameter $(2^{2m}(2^m + 2), 2^{2m} - 1, 2^{2m} - 2, 0)$.

By decomposing the cliques and the strongly regular graphs further, we show the existence of a symmetric association scheme with $2^{m+2} - 2$ classes and explain, by an example, how to find the first and second eigenmatrices of the scheme.

Clifton Cunningham (University of Calgary)

Dec 4, 2017

On the modularity conjecture for abelian varieties over \mathbb{Q}

The modularity theorem tells us that for every elliptic curve E over \mathbb{Q} , there is a modular form f_E such that the L-function $L(s, f_E)$ for f_E coincides with the L-function $L(s, \rho_E)$ for the Galois representation on the Tate module of E . In fact, f_E is a cusp form and its level is determined by the conductor of ρ_E . Since the modular form f_E determines an automorphic representation π_E of $\text{GL}_2(\mathbb{A}_{\mathbb{Q}})$ with the same L-function as f_E , we have

$$L(s, \rho_E) = L(s, \pi_E).$$

The modularity conjecture for abelian varieties is the obvious generalization of this theorem from the case of one-dimensional abelian varieties: For every abelian variety A over \mathbb{Q} there is an automorphic representation π_A of a group $G(\mathbb{A}_{\mathbb{Q}})$ such that

$$L(s, \rho_A) = L(s, \pi_A),$$

where ρ_A is the Galois representation on the Tate module of A .

In this talk I will describe recent joint work with Lassina Dembélé giving new instances of the modularity conjecture for abelian varieties over \mathbb{Q} . Where do we hunt for π_A ? What is the group G over \mathbb{Q} ? What is the level of π_A ? Can we find a generalized modular form f_A from which π_A can be built? I will explain how we use work of Benedict Gross, Freydoon Shahidi and others to answer these questions. I will also explain how thesis work by Majid Shahabi illuminates the level of π_A .

This is joint work with Lassina Dembélé.

Jan 9, 2017

Transversals in Latin arrays with many symbols

A transversal of a latin square of order n is a set of n entries picked in such a way that no row, column or symbol is present more than once. As you add more symbols to a latin square, you expect the number of transversals to increase. We show that once the number of symbols reaches a certain threshold, the square is guaranteed to have a transversal.

Non-vanishing of central values of Rankin-Selberg L -functions

In this talk, we discuss some results on the non-vanishing of the central values of Rankin-Selberg convolutions of families of Hilbert modular forms. Such results are obtained by establishing some asymptotics of certain twisted first and second moments. This is an on-going joint work with Naomi Tanabe.

Nathan Ng (Math and CS, U of Lethbridge)

Jan 30, 2017

A subconvexity bound in the t -aspect for degree two L -functions

Let f be a primitive modular form and $L_f(s)$ its associated L -function. Anton Good (1982) showed that $L_f(\frac{1}{2} + it) \ll |t|^{\frac{1}{3} + \varepsilon}$ in the case f is a modular form on the full modular group. In 1987, Matti Jutila gave a different proof and this was later refined by Martin Huxley. In this talk, we explain how the Jutila-Huxley approach can be generalized to the case of modular forms with arbitrary character χ , weight k , and level N . This is joint work with Andrew Booker (Bristol) and Micah Milinovich (Mississippi).

Joy Morris (Math and CS, U of Lethbridge)

Feb 6, 2017

Oriented Regular Representations

An oriented graph is a digraph with at most one arc between any pair of vertices. We say that the action of a group on a set of points is regular if it is sharply transitive; that is, there is exactly one group element mapping any point to any other point. An oriented regular representation (ORR) for a group G is an oriented graph whose automorphism group is isomorphic to the regular action of G on the vertices.

In 1980, Babai asked which groups admit an ORR. I will discuss this problem, and present joint work with Pablo Spiga in which we showed that every non-solvable group admits an ORR.

Explicit results in prime number theory

The prime number theorem, proven in 1896, is one of the first major theorems in analytic number theory. It provides estimates for prime counting functions. In 1962, Rosser and Schoenfeld gave a method to estimate the error term in the approximation of the prime counting function $\psi(x)$. Since then, progress on the numerical verification of the Riemann Hypothesis and widening the zero-free region of the Riemann zeta function have allowed numerical improvements of these bounds. In this talk, we present various new explicit methods such as introducing some smooth weights and establishing some zero density estimates for the Riemann zeta function. We also present some explicit results for primes in short intervals and for primes in arithmetic progressions.

Modern approach to the Traveling Salesman Problem

The Traveling Salesman Problem asks for the shortest route through a collection of cities. This classical problem is very hard, but, by applying Linear Programming (and other techniques), the optimal route has been found in test cases that have tens of thousands of cities. This talk will present some of the powerful methods that are explained in W. J. Cook's book "In Pursuit of the Traveling Salesman".

An association scheme for twin prime powers

Twin prime powers are used in the construction of some very interesting combinatorial objects. In an old paper they are used in the construction of regular Hadamard matrices. In a recent work, they are used to show the existence of an infinite class of Hadamard matrices lacking a certain algebraic structure.

In this talk I will discuss the use of twin prime powers in order to show the existence of a class of translation commutative association schemes. I will use the twin primes 3 and 5, as an example, to make the talk accessible to everyone.

Special values of Euler's function

In 1909, Landau showed that

$$\limsup \frac{n}{\phi(n) \log \log n} = e^\gamma,$$

where $\phi(n)$ is Euler's function. Later, Rosser and Schoenfeld asked whether there were infinitely many n for which $n/\phi(n) > e^\gamma \log \log n$. This question was answered in the affirmative in 1983 by Jean-Louis Nicolas, who showed that there are infinitely many such n both in the case that the Riemann Hypothesis is true, and in the case that the Riemann Hypothesis is false.

One can prove a generalization of Landau's theorem where we restrict our attention to integers whose prime divisors all fall in a fixed arithmetic progression. In this talk, I will discuss the methods of Nicolas as they relate to the classical result, and also provide evidence that his methods could be generalized in the same vein to provide answers to similar questions related to the generalization of Landau's theorem.

On the solutions of certain congruences

An odd prime p is called a *Wieferich prime* (in base 2), if

$$2^{p-1} \equiv 1 \pmod{p^2}.$$

These primes first were considered by A. Wieferich in 1909, while he was working on a proof of Fermat's last theorem. This notion can be generalized to any integer base $a > 1$. In this talk, we discuss the work that has been done regarding the size of the set of non-Wieferich primes and show that, under certain conjectures, there are infinitely many non-Wieferich primes in certain arithmetic progressions. Also we consider the congruence

$$a^{\varphi(m)} \equiv 1 \pmod{m^2},$$

for an integer m with $(a, m) = 1$, where φ is Euler's totient function. The solutions of this congruence lead to Wieferich numbers in base a . In this talk we present a way to find the largest known Wieferich number for a given base. In another direction, we explain the extensions of these concepts to other number fields such as quadratic fields of class number one. We also consider the solutions of the congruence

$$g^m - g^n \equiv 0 \pmod{f^m - f^n},$$

where m and n are two distinct natural numbers and f and g are two relatively prime polynomials with coefficients in the field of complex numbers. We prove this congruence has finitely many solutions.

Elliptic sequences

An *elliptic sequence* is a solution over an arbitrary integral domain of the recursion

$$W_{m+n} W_{m-n} = W_{m+1} W_{m-1} W_n^2 - W_{n+1} W_{n-1} W_m^2,$$

where $m, n \in \mathbb{Z}$. The theory of integral elliptic sequences was developed by Morgan Ward in 1948. We describe the fundamental classification theorem of Ward for these sequences. Our emphasis will be on the so called "singular" sequences and their relation to the classical Lucas sequences.

Hadi Kharaghani (Math and CS, U of Lethbridge) *The strongly regular graph $SRG(765, 192, 48, 48)$*

Sept 19, 2016

Andries Brouwer is 65 and a special issue of Designs, Codes and Cryptography is issued to celebrate the occasion.

Professor Brouwer maintains an elegant public database of existence results for all possible strongly regular graphs on $n \leq 1300$ vertices. In a very nice paper, Cohen and Pasechnik implemented most of the graphs listed there in the open source software Sagemath and obtained a graph for each set of parameters mentioned in the database. In their initial version of the paper, they mentioned 11 cases as *missing values*. A number of the cases were related to my work with professors Janko, Tonchev, and Ionin. I tried to help out with these cases and four cases were resolved quickly, after I sent detailed instructions. However, there was a problem with the case of $SRG(765, 192, 48, 48)$. This talk relates to this special case and a nice application of generalized Hadamard matrices.

To make the talk accessible to general audiences, I will provide many examples illustrating the concepts involved.

Farzad Aryan (Université de Montréal, Quebec) *On the zero free region of the Riemann zeta function*

Sept 26, 2016

We discuss the possibility that the Riemann zeta function has a zero $\sigma + iT$ to the left of the classical zero free region. We will show how the existence of this zero forces the function to have many more zeros in the vicinity of $\sigma + iT$ or/and $\sigma + 2iT$.

Dave Morris (Math and CS, U of Lethbridge) *Hamiltonian paths in projective checkerboards*

Oct 3, 2016

Place a checker in some square of an $m \times n$ rectangular checkerboard, and glue opposite edges of the checkerboard to make a projective plane. We determine whether the checker can visit all the squares of the checkerboard (without repeating any squares), by moving only north and east. This is joint work with Dallan McCarthy, and no advanced mathematical training will be needed to understand most of the talk.

Mikhail Muzychuk (Netanya Academic College, Israel)

Oct 17, 2016

Non-commutative association schemes of rank 6

An association scheme is a coloring of a complete graph satisfying certain regularity conditions. It is a generalization of groups and has many applications in algebraic combinatorics. Every association scheme yields a special matrix algebra called the Bose-Mesner algebra of a scheme. A scheme is called commutative if its Bose-Mesner algebra is commutative. Commutative schemes were the main topic of the research in this area for decades. Only recently non-commutative association schemes attracted the attention of researchers. In my talk I'll present the results about non-commutative association schemes of the smallest possible rank, rank 6. This is a joint work with A. Herman and B. Xu.

The sixth moment of the Riemann zeta function and ternary additive divisor sums

Hardy and Littlewood initiated the study of the $2k$ -th moments of the Riemann zeta function on the critical line. In 1918 Hardy and Littlewood established an asymptotic formula for the second moment and in 1926 Ingham established an asymptotic formula for the fourth moment. In this talk we consider the sixth moment of the zeta function on the critical line. We show that a conjectural formula for a certain family of ternary additive divisor sums implies an asymptotic formula for the sixth moment. This builds on earlier work of Ivic and of Conrey-Gonek.

Value-distribution of quadratic L -functions

We describe a theorem of M. Mourtada and V. Kumar Murty on the distribution of values of the logarithmic derivative of the L -functions attached to quadratic characters. Under the assumption of the generalized Riemann Hypothesis they prove the existence of a density function that gives the distribution of values of the logarithmic derivative of such L -functions at a fixed real point greater than $1/2$. Following classical results of Wintner, we also describe how this distribution can be described as an infinite convolution of local distributions.

Alia Hamieh (Math and CS, U of Lethbridge)

Nov 15, 2016

Value-distribution of cubic L -functions

In this talk, we describe a method for studying the value-distribution of L -functions based on the Jessen-Wintner theory. This method has been explored recently by Ihara and Matsumoto for the case of logarithms and logarithmic derivatives of Dirichlet L -functions of prime conductor and by Mourtada and V. K. Murty for the case of logarithmic derivatives of Dirichlet L -functions associated with quadratic characters. We show how to extend such results to the case of cubic characters. In fact, we describe a distribution theorem for the values of the logarithms and logarithmic derivatives of a certain family of Artin L -functions associated with cubic Hecke characters. This is a joint work with Amir Akbary.

Luke Morgan (University of Western Australia)

Nov 22, 2016

Permutation groups and graphs

The use of graphs to study permutation groups goes back to Higman who first introduced the orbital graphs, and used them to characterise the primitive groups. Since then, graph theory and permutation group theory have become intertwined, with many beautiful results. In this talk, I will discuss some problems which lie across the boundary of permutation group theory and graph theory (or at least algebraic graph theory), such as how to characterise a new class of permutation groups that includes the primitive ones - the so called semiprimitive groups.

Gabriel Verret (University of Auckland, New Zealand)

Nov 29, 2016

Vertex-primitive digraphs having vertices with almost equal neighbourhoods

A permutation group G on Ω is transitive if for every $x, y \in \Omega$ there exists $g \in G$ mapping x to y . The group G is called primitive if, in addition, it preserves no nontrivial partition of Ω . Let Γ be a vertex-primitive digraph, that is, its automorphism group acts primitively on its vertex-set. It is not hard to see that, in this case, Γ cannot have two distinct vertices with equal neighbourhoods, unless Γ is in some sense trivial. I will discuss some recent results about the case when Γ has two vertices with “almost” equal neighbourhoods, and how these results were used to answer a question of Araújo and Cameron about synchronising groups. (This is joint work with Pablo Spiga.)

Jan 25, 2016

On never primitive points on elliptic curves

The Lang-Trotter Conjecture for primitive points predicts an expression for the density of primes p for which a fixed rational point (not torsion) of a fixed elliptic curve defined on \mathbb{Q} is a generator of the curve reduced modulo p . After providing the definition of such a density in terms of Galois representations associated with torsion points of the curve, we will tell the short story of the contributions to the conjecture and provide examples of families of elliptic curves for which the conjecture holds for trivial reasons. This is the notion of “never primitive point.” The case of elliptic curves in complex multiplication will be discussed in greater detail. Part of the work is in collaboration of N. Jones.

Francesco Pappalardi (Università Roma Tre, Italy)

Jan 27, 2016

The distribution of multiplicatively dependent vectors

Let n be a positive integer, G be a group and let $\nu = (\nu_1, \dots, \nu_n)$ be in G^n . We say that ν is a multiplicatively dependent n -tuple if there is a non-zero vector (k_1, \dots, k_n) in \mathbb{Z}^n for which $\nu_1^{k_1} \dots \nu_n^{k_n} = 1$. Given a finite extension K of \mathbb{Q} , we denote by $M_{n,K}(H)$ the number of multiplicatively dependent n -tuples of algebraic integers of K^* of naive height at most H and we denote by $M_{n,K}^*(H)$ the number of multiplicatively dependent n -tuples of algebraic numbers of K^* of height at most H . In this seminar we discuss several estimates and asymptotic formulas for $M_{n,K}(H)$ and for $M_{n,K}^*(H)$ as $H \rightarrow \infty$. For each ν in $(K^*)^n$ we define m , the multiplicative rank of ν , in the following way. If ν has a coordinate which is a root of unity we put $m = 1$. Otherwise let m be the largest integer with $2 \leq m \leq n + 1$ for which every set of $m - 1$ of the coordinates of ν is a multiplicatively independent set. We also consider the sets $M_{n,K,m}(H)$ and $M_{n,K,m}^*(H)$ defined as the number of multiplicatively dependent n -tuples of multiplicative rank m whose coordinates are algebraic integers from K^* , respectively algebraic numbers from K^* , of naive height at most H and will consider similar questions for them.

Micah Milinovich (University of Mississippi)

Feb 1, 2016

Fourier Analysis and the zeros of the Riemann zeta-function

I will show how the classical Beurling-Selberg extremal problem in harmonic analysis arises naturally when studying the vertical distribution of the zeros of the Riemann zeta-function and other L -functions. Using this relationship, along with techniques from Fourier analysis and reproducing kernel Hilbert spaces, we can prove the sharpest known bounds for the number of zeros in an interval on the critical line and we can also study the pair correlation of zeros. Our results on pair correlation extend earlier work of P. X. Gallagher and give some evidence for the well-known conjecture of H. L. Montgomery. This talk is based on a series of papers which are joint with E. Carneiro, V. Chandee, and F. Littmann.

Alexey Popov (Math and CS, U of Lethbridge)

Feb 8, 2016

Operator algebras with reduction properties

An algebra is a vector space with a well-defined multiplication. An operator algebra is an algebra of operators acting on a Hilbert space, typically assumed closed in the norm topology. An easy example of an operator algebra is the algebra $M_n(\mathbb{C})$ of all the complex $n \times n$ matrices. In this colloquium-style talk, we will discuss operator algebras A with the following property: every A -invariant subspace is complemented by another A -invariant subspace. This property is called the Reduction property and is a kind of semisimplicity. We will discuss the connections of this property to some classical problems, such as Kadison Similarity Problem and the structure of amenable operator algebras.

Nathan Ng (Math and CS, U of Lethbridge)

Feb 22, 2016

Linear combinations of zeros of L -functions

The linear independence conjecture asserts that the multiset of positive ordinates of the zeros of automorphic L -functions is linearly independent over the field of rational numbers. This deep conjecture implies that if $1/2 + i\gamma$ is a zero of the Riemann zeta function, then $1/2 + 2i\gamma$ is not a zero of the zeta function. I will show that on the Riemann hypothesis this is true infinitely often. I will also discuss variants of this phenomenon. This is joint work with Greg Martin and Micah Milinovich.

Rob Craigen (University of Manitoba)
Survey of negacyclic weighing matrices

Feb 29, 2016

A square or rectangular matrix is circulant if every row after the first is a right circular shift of its predecessor. Negacyclic matrices are defined the same way except that the first entry of each row is negated after circulating the preceding row. A partial Hadamard matrix is a rectangular $k \times n$ $(1, -1)$ -matrix M satisfying $MM^T = nI$. In the summer of 2013 I hired four sharp undergraduate students to tackle a problem about circulant partial Hadamard matrices. The question of existence of certain negacyclic weighing matrices kept coming up, so we devoted some energy to exploring this largely uncultivated territory. In the end we produced, apparently for the first time, a fairly comprehensive survey of these objects, their structure, why certain classes exist and others cannot. The flavour of the existence questions for this class of weighing matrices is decidedly different from that of group-developed form, even though much of the theory is the same. We discuss some situations in which negacyclic weighing matrices naturally appear, and conclude with some tantalizing new open questions arising from the work.

Mar 7, 2016

Determining Hilbert modular forms by the central values of Rankin-Selberg convolutions

In this talk, we give a brief overview of adelic Hilbert modular forms. Then, we show that the central values of the Rankin-Selberg convolutions, $L(g \otimes f, s)$, uniquely determine an adelic Hilbert modular form g , where f varies in a carefully chosen infinite family of adelic Hilbert modular forms. We prove our results in both the level and weight aspects. This is a joint work with Naomi Tanabe.

Joy Morris (Math and CS, U of Lethbridge)

Mar 14, 2016

Automorphisms of circulant graphs

Determining the full automorphism group of a graph is a hard problem with a long history. I will discuss some of the major results that involve finding graphs with a given automorphism group. I will then focus on circulant graphs, and describe some structural results and algorithms that help us determine the full automorphism group of the graph. I will also give some asymptotic results about how many circulant graphs fall into different categories.

Arnab Bose (Math and CS, U of Lethbridge)

Mar 21, 2016

Investigations on some exponential congruences

Around 1981, Selfridge asked for what positive integers a and b does $2^a - 2^b$ divide $n^a - n^b$ for all $n \in \mathbb{N}$. The problem was independently solved by various people in different contexts. In this talk, we study their ideas and prove a generalization of the problem, in the elementary number theoretic sense and also in algebraic number fields. Further, we develop ideas to give a conditional resolution and generalizations to another problem by H. Ruderman which is closely related to Selfridge's problem.

Brandon Fuller (Math and CS, U of Lethbridge)

Apr 4, 2016

CCA groups and graphs

An automorphism of a Cayley graph that preserves its natural edge-colouring is called colour-preserving. We study groups G with the property that every automorphism on every connected Cayley graph on G is the composition of a left-translation and a group automorphism. We call this class of groups CCA groups and we look at classifying which groups are not CCA. More precisely, we look at abelian groups, groups of odd order and direct or semidirect products of groups.

Asif Zaman (University of Toronto, Ontario)

Apr 11, 2016

The least prime ideal in the Chebotarev Density Theorem

In 1944, Linnik famously showed unconditionally that the least prime in an arithmetic progression $a \pmod{q}$ with $(a, q) = 1$ is bounded by q^L for some absolute effective constant $L > 0$, known as “Linnik’s constant”. Many authors have computed explicit admissible values of L with the current world record at $L = 5$ by Xylouris (2011), refining techniques of Heath-Brown (1992). We consider a broad generalization of this problem in the Chebotarev Density Theorem (CDT), which is concerned with the splitting behaviour of prime ideals in number fields. Namely, what is the least norm of a prime ideal occurring in CDT. Papers of Lagarias-Montgomery-Odlyzko (1979) and Weiss (1983) give different unconditional field-uniform bounds but without any explicit exponents analogous to the subsequent work on Linnik’s constant. I will report on our recent work establishing such explicit estimates along with some applications related to primes represented by binary integral quadratic forms and congruences for Fourier coefficients of cuspidal Hecke eigenforms. This is joint work with Jesse Thorner.

Ram Murty (Queen’s University, Ontario)

June 17, 2016

Twin primes

We will discuss recent progress towards the twin prime conjecture as well as highlight some recent joint work with Akshaa Vatwani that connects the parity problem with the twin prime conjecture. The talk will be accessible to a wide audience.

June 28, 2016

Grosswald’s conjecture on primitive roots

Very little is known about the distribution of primitive roots of a prime p . Grosswald conjectured that the least primitive root of a prime p is less than $\sqrt{p} - 2$ for all $p > 409$. While this is certainly true for all p sufficiently large, Grosswald’s conjecture is still open. I shall outline some recent work which resolves the conjecture completely under the Generalised Riemann Hypothesis and which almost resolves the conjecture unconditionally.

Vijay Patankar (Jawaharlal Nehru University, India)

June 28, 2016

Pairs of elliptic curves and their Frobenius fields

Given an elliptic curve E over a number field K . The Frobenius field attached to E at a prime p is the splitting field of the characteristic polynomial of the Frobenius endomorphism acting on the ℓ -adic Tate module of E (ℓ a prime different from p) over the rationals. Thus, the splitting field is either of degree 1 or degree 2 over the rationals. Let E_1 and E_2 be elliptic curves defined over a number field K , with at least one of them without complex multiplication. We prove that the set of places v of K of good reduction such that the corresponding Frobenius fields are equal has positive upper density if and only if E_1 and E_2 are isogenous over some extension of K . For an elliptic curve E defined over a number field K , we show that the set of finite places of K such that the Frobenius field at v equals a fixed imaginary quadratic field F has positive upper density if and only if E has complex multiplication by F . Time permits we will provide a sketch of a result about two dimensional ℓ -adic Galois representations that we will need using an algebraic density theorem due to Rajan.

Sept 21, 2015

A two-part talk on (1) Sage mathematics software and (2) multiquadratic fields

This talk will be in two parts. It will begin with a short discussion of recent developments in the Sage Mathematics Software and some of the implications these developments may have for research in number theory world-wide. The second portion of this talk will focus on the structure of multiquadratic number fields, what we do and do not know about their integral bases, and how this knowledge may extend to understanding other rings of integers.

Dave Morris (Math and CS, U of Lethbridge)

Sept 28, 2015

What is a superrigid subgroup?

In combinatorial geometry (and engineering), it is important to know that certain scaffold-like geometric structures are rigid. (They will not collapse, and, in fact, have enough bracing that they cannot be deformed at all.) Replacing the geometric structure with an algebraic structure (namely, a group) leads to the following question: given a homomorphism that is defined on the elements of a subgroup, is it possible to extrapolate the homomorphism to the rest of the elements of the group? It is fairly obvious that every additive homomorphism from the group \mathbb{Z} of integers to the real line \mathbb{R} can be extended to a homomorphism that is defined on all of \mathbb{R} , and we will see some other examples.

Alexev Popov (Math and CS, U of Lethbridge)

Oct 5, 2015

Every operator has almost-invariant subspaces

It is a classical open problem in Operator Theory whether every bounded linear operator T on a Hilbert space H has a non-trivial invariant subspace (that is, a subspace Y of H such that TY is contained in Y ; nontrivial means not $\{0\}$ and not H). This is called the Invariant Subspace Problem; it is almost 100 years old. In this talk we will show that any bounded operator on an infinite-dimensional Hilbert space admits a rank one perturbation which has an invariant subspace of infinite dimension and co-dimension. Moreover, the norm of the perturbation can be chosen as small as needed. This is a joint work with Adi Teaciuc.

Oct 19, 2015

Special values of Rankin-Selberg L -functions

In this talk, we discuss some results on the non-vanishing in p -adic families of the central values of certain Rankin-Selberg L -functions (namely, anticyclotomic twists of L -functions) associated to automorphic forms on $GL(2)$.

Farzad Aryan (Math and CS, U of Lethbridge)

Oct 26, 2015

Gaps between zeros of the Riemann zeta function

The Riemann Hypothesis predicts that all zeros of the Riemann zeta function are located on the line $\Re(s) = \frac{1}{2}$. Also, we have that the number of zeros with imaginary parts located between T and $2T$ is approximately $\frac{T}{2\pi} \log T$. Therefore the average gap is about $\frac{2\pi}{\log T}$. It has been conjectured that there are gaps that are smaller than $\frac{2\pi c}{\log T}$, for every $c > 0$. This has been proven for c slightly larger than $\frac{1}{2}$. Proving that c can be taken less than $\frac{1}{2}$ seems to be a very hard problem, despite being far from the conjecture. In this talk we discuss the connection between Chowla's conjecture on the shifted convolution sums of the Liouville's function and the size of c .

Nathan Ng (Math and CS, U of Lethbridge)

Nov 2, 2015

The autocorrelation of a multiplicative function

Let h be a natural number and f an arithmetic function. The autocorrelation of f is the sum

$$C_f(x, h) = \sum_{n \leq x} f(n)f(n+h).$$

Such sums play an important role in analytic number theory. For instance, consider the classical arithmetic functions $\Lambda(n)$ (the von Mangoldt function), $\lambda(n)$ (Liouville's function), and $\tau_k(n)$ (the k -th divisor function). The sums $C_\Lambda(x, h)$, $C_\lambda(x, h)$, and $C_{\tau_k}(x, h)$ are related to the Twin Prime Conjecture, Chowla's conjecture, and to the moments of the Riemann zeta function, respectively. In this talk I will present a heuristic probabilistic method for deriving a conjecture for $C_f(x, h)$ in the case f is a multiplicative function.

Amir Akbary (Math and CS, U of Lethbridge)

Nov 6, 2015

Lang-Trotter Revisited

For a prime p , let $n(p)$ be the number of solutions (x, y) of $y^2 = x^3 + ax + b$ over the finite field \mathbb{F}_p and let $a(p) = p - n(p)$. In 1976, Serge Lang and Hale Trotter formulated a conjecture regarding the distribution of primes p for which $a(p) = A$ for a fixed integer A . In this talk we give an exposition of this conjecture as it is given in the introduction of a paper of Katz (N. Katz, Lang-Trotter Revisited, Bulletin of the AMS, Vol. 46, No. 3, July 2009, pp. 413–457).

Mohammad Bardestani (University of Ottawa, Ontario)

Nov 23, 2015

Isotropic quadratic forms and the Borel chromatic number of quadratic graphs

For a field F and a quadratic form Q defined on an n -dimensional vector space V over F , let over F , let G_Q , called the quadratic graph associated to Q , be the graph with the vertex set V where vertices v, w in V form an edge if and only if $Q(v-w) = 1$. Quadratic graphs can be viewed as natural generalizations of the unit-distance graph featuring in the famous Hadwiger-Nelson problem. In the present talk, we will prove that for a local field F of characteristic zero, the Borel chromatic number of G_Q is infinite if and only if Q represents zero non-trivially over F . The proof employs a recent spectral bound for the Borel chromatic number of Cayley graphs, combined with an analysis of certain oscillatory integrals over local fields. As an application, we will also answer a variant of question 525 proposed in the 22nd British Combinatorics Conference 2009.

Habiba Kadiri (Math and CS, U of Lethbridge)

Nov 30, 2015

Explicit bounds for $\psi(x; q, a)$

The prime number theorem in arithmetic progressions establishes that, for a and q fixed coprime integers, then $\psi(x; q, a)$ is asymptotic to $\frac{x}{\phi(q)}$ when x is large. We discuss new explicit

bounds for the error term $\left| \frac{\psi(x; q, a) - \frac{x}{\phi(q)}}{\frac{x}{\phi(q)}} \right|$, which provide an extension and improvement over

the previous work of Ramaré and Rumely. Such results depend on the zeros of the Dirichlet L -functions: a numerical verification of the Generalized Riemann Hypothesis up to a given height and explicit zero-free regions. We use the latest results of respectively Platt and Kadiri. In addition our method makes use of smooth weights. This is joint work with Allysa Lumley.

Joy Morris (Math and CS, U of Lethbridge)

Dec 7, 2015

Colour-permuting and colour-preserving automorphisms

A Cayley graph $Cay(G; S)$ on a group G with connection set $S = S^{-1}$ is the graph whose vertices are the elements of G , with $g \sim h$ if and only if $g^{-1}h \in S$. If we assign a colour $c(s)$ to each $s \in S$ so that $c(s) = c(s^{-1})$ and $c(s) \neq c(s')$ when $s' \neq s, s^{-1}$, this is a natural (but not proper) edge-colouring of the Cayley graph. The most natural automorphisms of any Cayley graph are those that come directly from the group structure: left-multiplication by any element of G ; and group automorphisms of G that fix S setwise. It is easy to see that these graph automorphisms either preserve or permute the colours in the natural edge-colouring defined above. Conversely, we can ask: if a graph automorphism preserves or permutes the colours in this natural edge-colouring, need it come from the group structure in one of these two ways? I will show that in general, the answer to this question is no. I will explore the answer to this question for a variety of families of groups and of Cayley graphs on these groups. I will touch on work by other authors that explores similar questions coming from closely-related colourings. This is based on joint work with Ademir Hujdurovič, Klavdija Kutnar, and Dave Witte Morris.

A subconvexity bound for modular L -functions

Let $L(s)$ be the L -function associated to a modular form of weight k for the full modular group. Using spectral theory, Anton Good proved that $L(k/2 + it) \ll t^{\frac{1}{3}}(\log t)^{\frac{5}{6}}$. Matti Jutila discovered a simpler proof which makes use of the Voronoi summation formula, exponential integrals, and Farey fractions. We shall present Jutila's argument.

Nathan Ng (Math and CS, U of Lethbridge)

Jan 26, 2015

A subconvexity bound for modular L -functions, part 2

This is a continuation of last week's talk. I will sketch Matti Jutila's proof of a subconvex bound for a modular L -function on the critical line. The main ideas are an approximate functional equation, the use of Farey fractions, Voronoi's summation formula, and exponential integral and sum estimates.

Nathan Ng (Math and CS, U of Lethbridge)

Feb 9, 2015

Gaps between the zeros of the Riemann zeta function

In this talk we will show how to exhibit large and small gaps between the zeros of the Riemann zeta function, assuming the Riemann hypothesis. This is based on a technique of Montgomery and Odlyzko. The problem of finding small gaps between the zeros leads to a very interesting optimization problem.

Gabriel Verret (University of Western Australia)

Mar 11, 2015

Zeros of L -functions

In 20th century, one of the most striking discoveries in number theory is Montgomery's pair-correlation. It says that pair-correlation of zeros of the Riemann zeta function is the same with that of eigenvalues of unitary matrices. In 1990's, Rudnick, Katz and Sarnak studied the zeros of L -functions more systematically. Moreover, Katz and Sarnak proposed the n -level density conjecture which claims that distributions of low-lying zeros of L -functions in a family is predicted by one of compact matrix groups, which are $U(N)$, $SO(\text{even})$, $SO(\text{odd})$, $O(N)$, and $Sp(2N)$. At the end of the talk, I will state an n -level density theorem for some families of Artin L -functions and talk about counting number fields with local conditions. I will start with a friendly definition of L -functions and give some examples. No background or knowledge for L -functions are required for this talk.

Daniel Vallieres (Binghamton University, New York)

Mar 13, 2015

Abelian Artin L -functions at zero

In the early 1970s, Harold Stark formulated a conjecture about the first non-vanishing Taylor coefficient at zero of Artin L -functions. About 10 years later, he refined his conjecture for abelian L -functions having order of vanishing one at zero, under certain hypotheses. In 1996, Karl Rubin extended this last refinement of Stark to the higher order of vanishing setting. In this expository talk for a general audience, we will give a survey of this area of research and present a more general conjecture, which we formulated in the past few years. At the end, we will present evidence for our conjecture and indicate one possible direction for further research.

Mar 23, 2015

Square totients

A well-known conjecture asserts that there are infinitely many primes p for which $p - 1$ is a perfect square. We obtain upper and lower bounds of matching order on the number of pairs of distinct primes $p, q \leq x$ for which $(p - 1)(q - 1)$ is a perfect square. This is joint work with Carl Pomerance (Dartmouth College).

Ram Murty (Queen's University, Ontario)

May 8, 2015

Consecutive squarefull numbers

A number n is called squarefull if for every prime p dividing n , we have p^2 also dividing n . Erdős conjectured that the number of pairs of consecutive squarefull numbers $(n, n + 1)$ with $n < N$ is at most $(\log N)^A$ for some $A > 0$. This conjecture is still open. We will show that the abc conjecture implies this number is at most N^ε for any $\varepsilon > 0$. We will also discuss a related conjecture of Ankeny, Artin and Chowla on fundamental units of certain real quadratic fields and discuss its connection with the Erdős conjecture. This is joint work with Kevser Aktas.

Adam Felix (KTH Royal Institute of Technology, Sweden)

June 1, 2015

How close is the order of a mod p to $p - 1$?

Let $a \in \mathbb{Z} \setminus \{0, \pm 1\}$, and let $f_a(p)$ denote the order of a modulo p , where $p \nmid a$ is prime. There are many results that suggest $p - 1$ and $f_a(p)$ are close. For example, Artin's conjecture and Hooley's subsequent proof upon the Generalized Riemann Hypothesis. We will examine questions related to the relationship between $p - 1$ and $f_a(p)$.

Darcy Best (Monash University, Australia)

June 15, 2015

Finding long transversals in Latin squares

A transversal of a latin square of order n is a subset of entries picked in such a way that each row, each column and each symbol is present at most once. In many latin squares, you can find a full transversal by selecting n entries which do not duplicate any row, column or symbol. But what about when you can't find a full transversal? Brualdi has conjectured that a transversal of length $n-1$ is always present in any latin square. In this talk, we will discuss recent work which shows that for small orders, Brualdi's conjecture holds. Moreover, we show that his conjecture also holds for small generalized latin squares as well.

Colour-permuting automorphisms of Cayley graphs

A Cayley graph $\text{Cay}(G; S)$ has the elements of G as its vertices, with $g \sim gs$ if and only if $s \in S$. There is a natural colouring of the edges of any such graph, by assigning colour s to an edge if it came from the element s of S . For a Cayley digraph, any graph automorphism that preserves this colouring has to be a group automorphism of G . For a Cayley graph, this is not the case. I will present examples of Cayley graphs that have automorphisms that do not correspond to group automorphisms of G . I will also show that for some families of groups, such examples are not possible. I will also discuss the more general problem of automorphisms that permute the colours, rather than necessarily preserving all of them.

Farzad Aryan (Math and CS, U of Lethbridge)

Sept 22, 2014

On binary and quadratic divisor problem

Let $d(n) = \sum_{d|n} 1$. This is known as the divisor function. It counts the number of divisors of an integer. Consider the following shifted convolution sum

$$\sum_{an-m=h} d(n)d(m)f(an, m),$$

where f is a smooth function which is supported on $[x, 2x] \times [x, 2x]$ and oscillates mildly. In 1993, Duke, Friedlander, and Iwaniec proved that

$$\sum_{an-m=h} d(n)d(m)f(an, m) = \text{Main term}(x) + O(x^{0.75}).$$

Here, we improve (unconditionally) the error term in the above formula to $O(x^{0.61})$, and conditionally, under the assumption of the Ramanujan-Petersson conjecture, to $O(x^{0.5})$. We will also give some new results on shifted convolution sums of functions coming from Fourier coefficients of modular forms.

Sept 29, 2014

Common divisors of the index and order of a modulo p

We study the distribution of primes for which the index and order of a modulo p have a fixed common divisor. We will also motivate this problem through previously known results related to Artin's conjecture for primitive roots.

Nathan Ng (Math and CS, U of Lethbridge)

Oct 6, 2014

Inclusive prime number races

Let $\pi(x; q, a)$ denote the number of primes up to x that are congruent to $a \pmod{q}$. A “prime number race”, for fixed modulus q and residue classes a_1, \dots, a_r , investigates the system of inequalities

$$\pi(x; q, a_1) > \pi(x; q, a_2) > \dots > \pi(x; q, a_r).$$

We expect that this system should have arbitrarily large solutions x , and moreover we expect the same to be true no matter how we permute the residue classes a_j ; if this is the case, the prime number race is called “inclusive”. Rubinstein and Sarnak proved conditionally that every prime number race is inclusive; they assumed not only the generalized Riemann hypothesis but also a strong statement about the linear independence of the zeros of Dirichlet L -functions. We show that the same conclusion can be reached with a substantially weaker linear independence hypothesis. This is joint work with Greg Martin.

Sean Fitzpatrick (Math and CS, U of Lethbridge)

Oct 20, 2014

Characters of induced representations

Let G be a compact semisimple Lie group, and let H be a closed subgroup of G . Given a linear representation $\tau : H \rightarrow \text{End}(V)$ of H , one can form an associated vector bundle $\mathcal{V}_\tau : \tau \rightarrow G/H$ over the homogeneous space G/H , and define an induced representation of G on the space of L^2 sections of \mathcal{V}_τ , after the method of Frobenius. Despite the resulting representation of G being infinite-dimensional, Berline and Vergne showed that it is possible to give a formula for its character. If we assume that H is a maximal torus in G , then G/H is a complex manifold, and the vector bundle \mathcal{V}_τ can be equipped with a holomorphic structure. In this case one can define the holomorphic induced representation of G by restricting to the space of holomorphic sections of \mathcal{V}_τ , which is a finite-dimensional vector space. We’ll show that both extremes can be viewed as special cases of a family of induced representations, whose characters can be computed as the index of a transversally elliptic operator on the homogeneous space G/H .

Kevin Henriot (University of British Columbia)

Oct 27, 2014

Linear equations in dense subsets of the squares.

We discuss the solvability of certain linear equations in sparse subsets of the squares. Specifically, we investigate equations of the form

$$\lambda_1 n_1^2 + \dots + \lambda_s n_s^2 = 0,$$

where $s \geq 7$ and the coefficients λ_i sum to zero and satisfy certain sign conditions. We show that such equations admit non-trivial solutions in any subset of $[N]$ of density $(\log N)^{-c_s}$, improving upon the previous best of $(\log \log N)^{-c}$.

Amir Akbary (Math and CS, U of Lethbridge)

Nov 3, 2014

Heuristics for some conjectural constants

We describe heuristics for several well-known density conjectures in prime number theory and elliptic curves theory. In each case we show how one can arrive at explicit expressions for density constants. The conjectures include twin prime conjecture, Bateman-Horn conjecture, Artin’s primitive root conjecture, and Koblitz-Zywina conjecture.

James Parks (Math and CS, U of Lethbridge)

Nov 10, 2014

Averages of the number of points on elliptic curves

Let E be an elliptic curve defined over \mathbb{Q} . Let $M_E(N)$ be the function that counts the number of primes p of good reduction such that $\#E(\mathbb{F}_p) = N$ where N is a fixed integer and $E(\mathbb{F}_p)$ denotes the group of points on the elliptic curve modulo p . We consider this function on average and discuss recent results related to the constant in the asymptotic result in the average.

Manoj Kumar (Math and CS, U of Lethbridge)

Nov 17, 2014

The signs in an elliptic net

Let R be an integral domain and let A be a finitely generated free abelian group. An elliptic net is a map $W: A \rightarrow R$ with $W(0) = 0$, and such that for all $p, q, r, s \in A$,

$$\begin{aligned} &W(p+q+s)W(p-q)W(r+s)W(r) \\ &+ W(q+r+s)W(q-r)W(p+s)W(p) \\ &+ W(r+p+s)W(r-p)W(q+s)W(q) \\ &= 0. \end{aligned}$$

In this talk we will give a formula to compute the sign of any term of an elliptic net without actually computing the value of that term.

Soroosh Yazdani (Google, Waterloo, Ontario)

Nov 21, 2014

Belyi maps and Diophantine equations

In 1979 G. Belyi proved that given any smooth curve C over any number field, there is map $\beta: C \rightarrow \mathbb{P}_1$ such that β is unramified outside of three points. This is particularly striking since Belyi's theorem is not true over complex numbers, and hence it is an arithmetic result as much as it is a geometric result. In this talk I will give a brief explanation for the proof of this theorem and explain how this theorem can be used to relate arithmetic geometry problems to the ABC conjecture.

Dave Morris (Math and CS, U of Lethbridge)

Dec 1, 2014

Introduction to arithmetic groups

We will discuss a few basic properties of “arithmetic groups,” which are certain groups of $n \times n$ matrices with integer entries. By definition, the subject combines algebra (group theory and matrices) with number theory (the integers), but it also has connections with other areas, including the theory of periodic tilings. To learn more about these interesting groups, download a free copy of my book from <http://arxiv.org/src/math/0106063/anc/>

Jan 20, 2014

A density increment approach to Roth's theorem in the primes

By combining Green and Tao's transference principle with a density increment argument, we show if A is a set of prime numbers satisfying $\sum_{a \in A} \frac{1}{a} = \infty$, then A must contain a 3 term arithmetic progression. The previous methods of Helfgott and De Roton, and the speaker, used the transference principle to move from a set of primes to a dense subset of integers by considering the L^2 and L^p -norms of a smoothed version of the indicator function of A . Instead, we work directly with the L^∞ -norm, and exploit the structure of A to obtain increased density on a large subprogression when A contains no arithmetic progressions. By iterating we show that for any constant $B > 0$, if A is a subset of primes contained in $\{1, \dots, N\}$ with size at least $|A| \gg_B \frac{N}{\log N (\log \log N)^B}$, then A contains a three term arithmetic progression.

Mohammadreza Jooyandeh (Australian National University)

Jan 27, 2014

Recursive algorithms for generation of planar graphs

In this talk we introduce recursive algorithms for generation of three families of plane graphs. These algorithms start with small graphs and iteratively convert them to larger graphs. The families are k -angulations (plane graphs with whose faces are of size k), plane graphs with a given face size sequence and planar hypohamiltonian graphs. Hypohamiltonian graphs have the property that removing each vertex from the graph, there is a Hamiltonian cycle through all remaining vertices while the original graph does not have any such cycle. One of the problems in the literature since 1976 is to find the smallest planar hypohamiltonian graphs. The previous record by Weiner and Araya was a planar graph with 42 vertices. We improve this record by finding 25 planar hypohamiltonian graphs on 40 vertices while discovering many larger ones on 42 and 43 vertices. We also introduce a very fast method for canonical embedding and isomorphism rejection of plane graphs. Most graph generators like plantri generate graphs isomorph-free up to isomorphism of the embedding, however our method does the isomorphism checking up to the underlining graph while taking advantage of the planarity and embeddings to speed up the computation.

David Roe (University of Calgary)

Feb 3, 2014

Numerical methods in p -adic linear algebra

Standard numerical methods focus on algorithms for matrices over the real and complex numbers: finding singular value decompositions, eigenvalues and eigenvectors, QR and LU decompositions. Many of the same questions make sense for non-archimedean local fields, and some methods carry over. Moreover, the ultrametric properties of p -adic arithmetic allow for much better tracking of precision than in the real and complex cases. This is a report on early stages of joint work with Xavier Caruso, Tristan Vaccon, Jen Balakrishnan and Kiran Kedlaya.

Joy Morris (Math and CS, U of Lethbridge)

Feb 10, 2014

Automorphisms of Cayley graphs that respect partitions

A Cayley graph $\Gamma = \text{Cay}(G; S)$ on a group G with connection set S , is a graph whose vertices are labelled with the elements of G , with vertices g_1 and g_2 adjacent if $g_1^{-1}g_2 \in S$. We say that an automorphism α of Γ respects the partition \mathcal{C} of the edge set of Γ if for every $C \in \mathcal{C}$, we have $\alpha(C) \in \mathcal{C}$. I will discuss some obvious partitions of the edge set of a Cayley graph Γ , and find conditions under which a graph automorphism of Γ that respects these partitions and fixes a vertex, must be an automorphism of the group G .

Olivier Ramaré (CNRS and Université de Lille 1, France)

Feb 24, 2014

Bilinear forms on prime numbers

This talk will retrace the main steps of the modern theory of prime numbers and in particular how the combinatorial sieve combined with the Dirichlet series theory to give birth to the modern representation of the primes via a linear combination of terms, some of which being “linear”, while the other ones are “bilinear”. This will lead us to the recent developments of Green and Tao, Mauduit and Rivat, Tao, Helfgott, and Bourgain, Sarnak and Ziegler.

Daniel Fiorilli (University of Michigan)

Mar 3, 2014

Nuclear physics and number theory

While the two fields named in the title seem unrelated, there is a strong link between them. Indeed, random matrix theory makes predictions in both fields, and some of these predictions can be verified rigorously on the number theory side. This amazing connection came to life during a meeting between Freeman Dyson and Hugh Montgomery at the Institute for Advanced Study. Random matrices are now known to predict many statistics about zeta functions, such as moments, low-lying zeros and correlations between zeros. The goal of this talk is to discuss this connection, focusing on number theory. We will cover both basic facts about the zeta functions and recent developments in this active area of research.

Amir Akbary (Math and CS, U of Lethbridge)

Mar 10, 2014

Introduction to the ABC Conjecture

We will describe the celebrated ABC conjecture, due to Oesterle and Masser, formulated in 1985. We will explain one of the motivations behind this conjecture and discuss a refinement of this conjecture put forward by Baker in 1996.

Hadi Kharaghani (Math and CS, U of Lethbridge)

Mar 17, 2014

Difference matrices and applications

Let (G, \odot) be a group of order g . A $(g, k; \lambda)$ - difference matrix is a $k \times g\lambda$ matrix $D = (d_{ij})$ with entries from G , so that for each $1 \leq i < j \leq k$, the multiset

$$\{d_{il} \odot d_{jl}^{-1} : 1 \leq l \leq g\lambda\}$$

(the difference list) contains every element of $G\lambda$ times. A generalized Hadamard matrix $GH(g, \lambda)$ is a $(g, g\lambda; \lambda)$ -difference matrix. Some interesting examples of difference matrices and generalized Hadamard matrices with emphasis on their applications will be discussed.

Ted Dobson (Mississippi State University)

Mar 24, 2014

On Cayley Numbers

In 1983, Marušič posed the problem of determining which positive integers n have the property that every vertex-transitive graph of order n is isomorphic to a Cayley graph of some group. Such an integer n is called a Cayley number. Much work on this problem has been done, and, for example, it is known exactly which integers divisible by a square are Cayley numbers. These are p^2 , p^3 , and 12. Additionally, a fair amount is known via constructions about which square-free integers are not Cayley numbers. Much less is known about which square-free integers are Cayley numbers, and it is not even known if there is a Cayley number that is a product of five distinct primes. We answer a question posed by C. Praeger who asked if there was a Cayley number of order n where n has k distinct prime factors for every positive integer k . We construct an infinite set of distinct prime numbers S with the property that the product of any k elements of S is always a Cayley number. This is joint work with Pablo Spiga.

Allysa Lumley (Math and CS, U of Lethbridge)

Mar 31, 2014

New bounds for $\psi(x; q, a)$

Let a, q be relatively prime integers. Then consider

$$\psi(x; q, a) = \sum_{\substack{n \leq x \\ n \equiv a \pmod{q}}} \Lambda(n).$$

We discuss new explicit bounds for $\psi(x; q, a)$, which provide an extension and improvement over the bounds given in the previous work of Ramaré and Rumely. This article introduces two new ideas. We smooth the prime counting function and use the partial verification of GRH by Platt along with an explicit zero-free region given by Kadiri. This is joint work with Habiba Kadiri.

James Parks (Math and CS, U of Lethbridge)

Apr 7, 2014

Amicable pairs and aliquot cycles on average

Let E be an elliptic curve defined over \mathbb{Q} . A pair (p, q) of distinct prime numbers is called an amicable pair of E if E has good reduction at p and q and $\#E_p(\mathbb{F}_p) = q$ and $\#E_q(\mathbb{F}_q) = p$. In this talk we show a non-trivial upper bound for the number of amicable pairs on average over a family of elliptic curves.

Soroosh Yazdani (Math and CS, U of Lethbridge)

Apr 14, 2014

Modular curves and moduli problems

Modular curves are the parameter space of elliptic curves with certain torsion structure. In this talk, I will explain what that sentence means, and how it is related to the usual definition of modular curves in terms of quotients of the complex upper half plane with certain matrix groups.

Sept 16, 2013

On distribution of squares modulo a composite number q

A natural number s is said to be a square modulo a composite number q if it is a square modulo each of the prime numbers dividing q . Let p be a prime number, then

$$\text{Prob}(s \text{ is a square mod } p) = p + \frac{1}{2p} \approx \frac{1}{2}.$$

Roughly speaking, the probability of a number to be a square modulo q is $\frac{1}{2^{\omega(q)}}$, where $\omega(q)$ is the number of prime divisors of q .

Fix h and let $X : \{1, 2, \dots, q\} \rightarrow \mathbb{N}$ be a random variable, given by

$$X(i) = \#\{s \in [i, i+h] : s \text{ is a square modulo } q\}.$$

For the mean, we have $E(X) \approx \frac{h}{2^{\omega(q)}}$, and, in this talk, we show the following bound for the variance: $\text{Var}(X) \leq E(X) \approx \frac{h}{2^{\omega(q)}}$.

Nathan Ng (Math and CS, U of Lethbridge)

Sept 23, 2013

Zhang's theorem on bounded gaps between primes

In Apr 2013, Yitang Zhang announced one of the great theorems in the history of number theory. He showed there exists an absolute constant C such that infinitely many consecutive primes differ by C . This theorem goes a long way towards proving the twin prime conjecture. In this talk I will give an overview of Zhang's theorem and some of the main ideas in the proof.

Nathan Ng (Math and CS, U of Lethbridge)

Sept 30, 2013

Zhang's theorem on bounded gaps between primes, part 2

In this talk, I will focus on the Goldston-Pintz-Yildirim (GPY) method for detecting small gaps between primes. In particular, I will discuss the choice of weight function in their optimization argument and the role of primes in arithmetic progressions. Finally, we will consider the Motohashi-Pintz/Zhang variant of the GPY argument which yields bounded gaps between primes.

Jeff Bleaney (Math and CS, U of Lethbridge)

Oct 7, 2013

Symmetries of an elliptic net

In 1948, Morgan Ward introduced the concept of an Elliptic Divisibility Sequence (EDS) as an integer sequence (W_n) which satisfies the recurrence relation

$$W_{m+n}W_{m-n}W_1^2 = W_{m+1}W_{m-1}W_n^2 - W_{n+1}W_{n-1}W_m^2,$$

and satisfies the additional property that $W_m \mid W_n$ whenever $m \mid n$. Of particular interest to Ward, were what he called symmetries of an EDS. Ward showed that if (W_n) is an EDS with $W_r = 0$, then we have $W_{r+i} = ab^i W_i$, for some a and b . In her Ph.D. thesis in 2008, Kate Stange generalized the concept of an EDS to an n -dimensional array called an Elliptic Net.

We will discuss the connections between EDS's, Elliptic Nets, and elliptic curves, and give a generalization of Ward's symmetry theorem for elliptic nets.

Adam Felix (Math and CS, U of Lethbridge)

Oct 21, 2013

On the distribution of torsion points modulo primes

We will discuss a paper of Chen and Kuan, in which they study the distribution of torsion points modulo primes over several different commutative algebraic groups. They demonstrate that the average is related to some generalized divisor function for these groups.

Dave Morris (Math and CS, U of Lethbridge)

Oct 28, 2013

What is a Coxeter group?

Coxeter groups arise in a wide variety of areas, so every mathematician should know some basic facts about them, including their connection to "Dynkin diagrams." Proofs about these "groups generated by reflections" mainly use group theory, geometry, and combinatorics.

Soroosh Yazdani (Math and CS, U of Lethbridge)

Nov 4, 2013

Solving S -unit equations

Let S be a finite collection of prime numbers. We say a number is an S -unit if it is a product of powers of primes in S . For instance $-\frac{3}{8}$ is an example of a $\{2, 3\}$ -unit. Many interesting Diophantine equations are reduced to solving equations of the form $x+y=1$ with x and y both being an S -unit. Using linear forms of logarithms, we can show that there only finitely many solutions to these S -unit equations. In this talk, I will explain an algorithm (due primarily to Smart and Wildanger) on how we can actually enumerate all these solutions.

Patrick Ingram (Colorado State University)

Nov 15, 2013

The arithmetic of post-critically finite morphisms

Let f be an endomorphism of N -dimensional projective space. In complex dynamics, it has been known for a century (at least when $N = 1$) that the orbits of the critical points determines much of the dynamics of f . Morphisms for which all of these critical orbits are finite (so-called PCF maps) turn out to be an important class to understand. Thurston proved, when $N = 1$, that there are no algebraic families of PCF maps, except for a small number of easy-to-understand examples. I will discuss some recent research into the arithmetic properties of these maps, as well as a partial extension of Thurston's result to arbitrary dimension.

James Parks (Math and CS, U of Lethbridge)

Nov 18, 2013

Distribution conjectures for elliptic curves on average

Let E be an elliptic curve over \mathbb{Q} . In this talk we consider several open conjectures about the distribution of local invariants associated with the reductions of E modulo p as p varies over the primes. In order to gain evidence for the conjectures, we consider them on average over a family of elliptic curves.

Habiba Kadiri (Math and CS, U of Lethbridge)

Nov 25, 2013

Zero density and primes

In this talk we present some new Chebyshev bounds for the function $\psi(x)$. In 1962, Rosser and Schoenfeld provided a method to estimate the error term in the approximation $|\psi(x) - x|$. Since then, progress on the numerical verification of the Riemann Hypothesis and widening the zero-free region have allowed to improve numerically these bounds. In this talk we present a new method by introducing a smooth weight and by using the first explicit zero density estimate for the Riemann zeta function. We also present new results for primes in short intervals, based on this zero density estimate.

Darcy Best (Math and CS, U of Lethbridge)

Dec 2, 2013

Biangular lines

A set of unit vectors $V \subset \mathbb{C}^n$ is called biangular if for any $u, v \in V$, $u \neq v$,

$$|\langle u, v \rangle| \in \{0, \alpha\}$$

for some $0 < \alpha < 1$. There are well-known upper bounds on the size of these sets of vectors. We will discuss these upper bounds, and the implications when they are met, including the generation of combinatorial objects such as strongly regular graphs and association schemes.

Renate Scheidler (University of Calgary)

Dec 9, 2013

Continued fractions with bounded period length

It is well-known that the continued fraction expansion of a quadratic irrational is horizontally symmetric about its centre. However, an additional vertical symmetry is exhibited by the continued fraction expansions arising from a certain one-parameter family of positive integers known as Schinzel sleepers. This talk provides a method for generating any Schinzel sleeper and investigates their period lengths as well as both their horizontal and vertical symmetries.

This is joint work with Kell Cheng (Hongkong Institute of Education) as well as Richard Guy and Hugh Williams (University of Calgary). The talk is geared toward an audience with a background corresponding to no more than a first number theory course.

Jan 21, 2013

Shimura-Taniyama conjecture / modularity theorems – an overview

Shimura-Taniyama conjecture (now known as modularity theorem) states that all rational elliptic curves are modular. Despite its technical sounding statement, this conjecture became famous due to its application to Fermat's last theorem. Thanks the work of Wiles and others, not only we know that all rational elliptic curves are modular, we also know that many other generalizations (for example, Q -curves) are also modular. However, what do we mean by "all rational elliptic curves are modular", and how would one go about proving such a statement?

In this talk I will explain what we mean by modularity of an elliptic curve using Galois representation, and provide some (a.k.a. epsilon amount) hint on how one can prove the modularity theorems.

Hadi Kharaghani (Math and CS, U of Lethbridge)

Jan 28, 2013

The asymptotic existence of Hadamard matrices

A square ± 1 -matrix with orthogonal rows is called a *Hadamard matrix*. It is conjectured that a Hadamard matrix of order $4n$ exists for each natural number n . A result of Seberry [1976] states that:

For any positive integer p there is a Hadamard matrix of order 2^np for every $n \geq [2\log_2(p-3)]$.

Rob Craigen, while in our department in 1994, improved this result considerably by showing that:

There exists a circulant signed group Hadamard matrix of every even order n , using a suitable signed group. This in turn would imply the existence of Hadamard matrices of order 2^np for every $n \geq 4[(1/6)\log_2((p-1)/2)] + 2$.

These and other asymptotic results will be discussed.

Error terms and sums of independent random variables

The normalized error term in the prime number theorem is intimately related to the location of the zeros of the zeta function. In 1901, Von Koch proved that the Riemann hypothesis implies that this error term is less than $\log^2 x$. In 1914, Littlewood famously proved that the error term is infinitely often larger than $\log \log \log x$. Which function is closer to the truth? In important work, Montgomery suggested that the truth lies near $(\log \log \log x)^2$. His work depends on modelling the normalizing error term by a sum of independent random variables. He then derives sharp estimates for large deviations of this sum of independent random variables. I will attempt to explain the main ideas behind his conjecture.

Adam Felix (Math and CS, U of Lethbridge)

Feb 11, 2013

Artin's Conjecture on primitive roots

A primitive root modulo a prime p is an integer which generates the group of non-zero residues modulo p . For primes p , we can always find a primitive root modulo p . In 1927, Artin conjectured that a density for the set of primes for which a fixed integer is a primitive root modulo p exists. Hooley showed that this is true upon the generalized Riemann hypothesis. I will give two conditional proofs of this result: Hooley's original proof and a proof which generalizes to other problems related to Artin's conjecture.

Chebyshev bias for elliptic curves

Recently, there's been a lot of talk about a result of Fiorilli, relating Chebyshev bias for elliptic curves and ranks of elliptic curves, during coffee hour. At the time of discussion all we had at our disposal was a vague abstract from a talk that Fiorilli gave at AMS in San Diego, so I had a hard time figuring out what was going on. As luck would have it, few weeks ago, I saw a talk of William Stein relating Chebyshev bias and ranks of elliptic curves, and this past week Fiorilli sent a preprint to Farzad. This talk will try to summarize all of these recent developments. In particular, I will describe what we mean by Chebyshev's bias for elliptic curves, and how this bias is related to the (analytic) rank of an elliptic curve.

Mar 4, 2013

Introduction to vertex-transitive graphs of prime-power order

A graph is *vertex-transitive* if its automorphism group acts transitively on the set of vertices. (In other words, every vertex looks exactly like all of the other vertices.) Such graphs can be very complicated in general, but we will use some group theory to see that they are easy to describe when the number of vertices is assumed to be prime. There are similar results when the number of vertices is the square or cube of a prime, but larger powers are harder to understand.

Farzad Aryan (Math and CS, U of Lethbridge)

Mar 11, 2013

On sums and products of integers

Additive combinatorics has recently attracted a lot of attention in the mathematics world. A famous conjecture in this field, known as Erdős and Szemerédi's conjecture, concerns the sums and products of integers. It asserts the following:

Conjecture. For any fixed $\delta > 0$ the lower bound

$$\max\{|A + A|, |A \cdot A|\} \gg_{\delta} |A|^{2-\delta}$$

holds for all finite sets $A \subset \mathbb{Z}$.

Here $A + A = \{a + a' : a, a' \in A\}$ and $A \cdot A = \{aa' : a, a' \in A\}$.

Roughly speaking, the conjecture states that: For a fixed a set of integers, both the sum-set and product-set cannot be small. There are two major achievements towards this conjecture which we discuss during the talk:

- (1) Chang in 2003 showed that the sum-set must be large whenever the product-set is sufficiently small. More precisely, she has shown that

$$|A + A| > 36^{-\alpha} |A|^2$$

if $|A \cdot A| < \alpha |A|$ for some constant α .

- (2) The best known bound today, achieved by Solymosi, follows from his more general inequality

$$|A + A|^2 |A \cdot A| \geq \frac{|A|^4}{2 \log |A|}.$$

The Solymosi's result is valid for A a finite subset of the real numbers. From the inequality we have

$$\max\{|A + A|, |A \cdot A|\} \geq \frac{|A|^{4/3}}{2(\log |A|)^{1/3}}.$$

Mar 18, 2013

The asymptotic existence of orthogonal designs

A *complex orthogonal design* of order n and type (s_1, \dots, s_k) , denoted $COD(n; s_1, \dots, s_k)$, is a matrix X with entries from $\{0, \epsilon_1 x_1, \dots, \epsilon_k x_k\}$, where the x_i 's are commuting variables and $\epsilon_j \in \{\pm 1, \pm i\}$ for each j , that satisfies

$$XX^* = \left(\sum_{i=1}^k s_i x_i^2 \right) I_n,$$

where X^* denotes the conjugate transpose of X and I_n is the identity matrix of order n .

A complex orthogonal design in which $\epsilon_j \in \{\pm 1\}$ for all j is called an *orthogonal design*, denoted $OD(n; s_1, \dots, s_k)$. An orthogonal design (=OD) in which there is no zero entry is called a *full OD*. Equating all variables to 1 in any full OD results in a *Hadamard* matrix.

In this seminar, we show that for any n -tuple (s_1, \dots, s_k) of positive integers, there exists an integer N such that for each $n \geq N$, there is an $OD\left(2^n(s_1 + \dots + s_k); 2^n s_1, \dots, 2^n s_k\right)$. This is a joint work with professor Hadi Kharaghani.

Amir Akbary (Math and CS, U of Lethbridge)

Mar 25, 2013

Sets of multiples

For a subset S of natural numbers we consider its set of multiples $M(S)$. So

$$M(S) = \{ms; m \in \mathbb{N}, s \in S\}.$$

In many cases we can see that $M(S)$ has an asymptotic density $\delta(M(S))$. For example if $S = \{2, 3\}$ then $\delta(M(S)) = 2/3$.

Question. *Is it true that $\delta(M(S))$ exists for any $S \subseteq \mathbb{N}$?*

The following conjecture was formulated around 1930's.

Conjecture. *$\delta(M(S))$ exists for any $S \subseteq \mathbb{N}$.*

By 1934 the answer to the above question was known. In this talk we study this question.

Hadi Kharaghani (Math and CS, U of Lethbridge)

Apr 8, 2013

The maximum determinant problem

Consider the set M_n of all matrices of order n with entries -1 and 1 . The set $D_n = \{\det(A) : A \in M_n\}$ is a finite subset of integers. The maximum determinant problem deals with α_n ; the largest possible value of the set D_n . The study of this (relatively old) problem has led people to some very interesting results and questions in number theory, combinatorics and statistics.

The following inequalities and the cases where equalities are attained will be discussed.

- (1) For $n \equiv 0 \pmod{4}$, $\alpha_n \leq n^{n/2}$. Equality occurs iff there is a $(1, -1)$ -matrix H of order n with $HH^t = nI_n$.
- (2) For odd n , $\alpha_n \leq \sqrt{2n-1} (n-1)^{(n-1)/2}$. Equality occurs iff there is a $(1, -1)$ -matrix A with $AA^t = A^tA = (n-1)I_n + J_n$.
- (3) For $n \equiv 2 \pmod{4}$, $\alpha_n \leq (2n-2)(n-2)^{(n-2)/2}$. Equality occurs iff there is a $(1, -1)$ -matrix B with

$$BB^t = B^tB = \begin{pmatrix} M & 0 \\ 0 & M \end{pmatrix},$$

where $M = (n-2)I_{n/2} + 2J_{n/2}$.

Joy Morris (Math and CS, U of Lethbridge)

Apr 15, 2013

How big is the automorphism group of a generic circulant (di)graph?

A circulant (di)graph is a (di)graph that can be drawn with its n vertices equally spaced around a circle, in such a way that rotation by $360/n$ degrees is a symmetry. It is not hard to see that in the case of a graph, reflection is also a symmetry, so the automorphism group (the group of all of its symmetry operations) must contain the dihedral group of order $2n$.

I will present results showing that for almost all circulant (di)graphs, these are the only symmetries. I will then look at what we can say about the automorphism group of a circulant (di)graph that has more symmetry than this.

This will draw on work by Babai, Godsil, Dobson, Bhoomik, and myself.

Joy Morris (Math and CS, U of Lethbridge)

Sept 17, 2012

Calculating partition numbers

The partition number $p(n)$ is the number of ways that n can be partitioned into a sum of smaller positive integers. At the SIAM Discrete Math conference in June, I attended a plenary talk by Ken Ono of Emory on how to calculate partition numbers. This topic incorporates both combinatorics and number theory. Ken Ono was kind enough to give me a copy of his slides so that I could present this topic in our seminar, and I will be using those slides for this talk.

Amir Akbary (Math and CS, U of Lethbridge)

Sept 24, 2012

On a conjecture of Erdős

Let m be an integer bigger than 1 and let $P(m)$ denote the largest prime divisor of m . In 1962, Erdős conjectured that

$$\lim_{n \rightarrow \infty} \frac{P(2^n - 1)}{n} = \infty.$$

In 2000, Ram Murty and Siman Wong conditionally resolved this conjecture, under the assumption of a celebrated conjecture in number theory. In this talk I will describe their work.

Dave Morris (Math and CS, U of Lethbridge)

Oct 1, 2012

Hamiltonian paths in solvable Cayley digraphs

Cayley graphs are very nice graphs that are constructed from finite groups. If the group is abelian, then it is easy to show that the graph has a hamiltonian cycle. It is conjectured that the nonabelian Cayley graphs also have hamiltonian cycles.

We will discuss a few recent results (both positive and negative) on the related problem where the graph is replaced by a directed graph, and the finite group is assumed to be solvable (which means it is not too far from being abelian).

Soroosh Yazdani (Math and CS, U of Lethbridge)

Oct 15, 2012

Local Szpiro conjecture

The Szpiro conjecture is one of the big conjectures in number theory and Diophantine equations. It is equivalent to the ABC conjecture, and so it implies many interesting results. In this talk I will mention a conjecture that is motivated by the Szpiro conjecture, which seems much less strong than the Szpiro conjecture, even though it still has many interesting Diophantine applications. We will also present a few cases where we can prove this conjecture.

Nathan Ng (Math and CS, U of Lethbridge)

Oct 22, 2012

Additive divisor sums

The divisor function $d(n)$ equals the number of divisors of an integer n . In this talk I will discuss what is known about additive divisor sums of the shape

$$D(N, r) = \sum_{n \leq N} d(n)d(n+r)$$

where r is a fixed positive integer. These sums were introduced by Ingham in 1926, who proved an upper bound for $D(N, r)$. This was later refined to an asymptotic formula by Estermann and over the years was further sharpened by a succession of authors, including Heath-Brown, Deshouillers and Iwaniec, Motohashi, and Meurman. More recent evaluations of $D(N, r)$ makes use of the spectral theory of automorphic forms. I will also discuss more general additive divisor sums of the shape

$$D_k(N, r) = \sum_{n \leq N} d_k(n)d_k(n+r)$$

where k is a natural number larger than 2 and where $d_k(n)$ equals the number of ordered k -tuples (n_1, \dots, n_k) such that $n = n_1 \cdots n_k$.

Oct 29, 2012

Weil conjectures

In 1949, Weil proposed a set of conjectures about the generating functions which are derived from counting the number of points on an algebraic variety over a finite field. Solving Weil's conjectures was one of the central mathematics projects of the twentieth century. These problems were totally solved by a group of people including Dwork, Grothendieck, and Deligne.

In this talk, we present a historical background and state the assertions of Weil conjectures. We further explain some sentences about the ideas of the proofs.

Farzad Aryan (Math and CS, U of Lethbridge)
The distribution of k -tuples of reduced residues

Nov 5, 2012

Let q be a natural number, and write $P = \varphi(q)/q$, that is P is the probability that a randomly chosen integer is relatively prime to q . Let

$$1 = a_1 < a_2 < \cdots < a_{\phi(q)} < q$$

be the reduced residues mod q (integers co-prime to q in increasing order). A quantity of central interest is

$$V_\gamma(q) = \sum_{i=1}^{\phi(q)} (a_{i+1} - a_i)^\gamma.$$

In 1940, Erdős conjectured that

$$V_\gamma(q) \ll qP^{1-\gamma}.$$

Let $\mathcal{D} = \{h_1, h_2, \dots, h_s\}$ be an admissible set. We call $a + h_1, \dots, a + h_s$ an s -tuple of reduced residues, if each of these numbers is co-prime with q . Study of s -tuples of reduced residues is an analogue to the study of s -tuples of primes. In this talk we prove estimates about the distribution of s -tuples of reduced residues and finally we prove an extension of Erdős's conjecture for s -tuples:

$$V_\gamma^{\mathcal{D}}(q) := \sum_{a_i < q} (a_{i+1} - a_i)^\gamma \ll qP^{-s(\gamma-1)},$$

where the sum runs over the integers $1 = a_1 < a_2 < \cdots < q$ for which $a_i + h_1, \dots, a_i + h_s$ is an s -tuple of reduced residues.

Chris Godsil (University of Waterloo, Ontario)
Continuous quantum walks on graphs

Nov 23, 2012

If A is the adjacency matrix of a graph X , then the matrix exponential $U(t) = \exp(itA)$ determines what physicists term a continuous quantum walk. They ask questions such as: for which graphs are there vertices a and b and a t such that $|U(t)_{a,b}| = 1$? The basic problem is to relate the physical properties of the system with properties of the underlying graphs, and to study this we make use of results from the theory of graph spectra, number theory, ergodic theory.... My talk will present some of the progress on this topic.

Heinz Bauschke (University of British Columbia – Okanagan)
An Invitation to projection models

Nov 30, 2012

Feasibility problems, i.e., finding a solution satisfying certain constraints, are common in mathematics and the natural sciences. If the constraints have simple projectors (nearest point mappings), then one popular approach to these problems is to use the projectors in some algorithmic fashion to approximate a solution. In this talk, I will survey three methods (alternating projections, Dykstra, and Douglas-Rachford), and comment on recent advances and remaining challenges.

Mark Thom (Math and CS, U of Lethbridge)
Squarefree values of trinomial discriminants

Dec 3, 2012

The discriminant of a trinomial of the form $x^n \pm x^m \pm 1$ has the form $\pm n^n \pm (n - m)^{n-m} m^m$ when n and m are co-prime. We determine necessary and sufficient conditions for identifying primes whose squares never divide the discriminants arising from coprime pairs (n, m) . These conditions are adapted into an exhaustive search method, which we use to corroborate a heuristic estimate of the density of all such primes among the odd primes. The same results are used to produce a heuristic estimate of the density of squarefree values of these discriminants. We'll also look at an unlikely seeming family of divisors of the discriminants, arising from an elementary identity on them. This is joint work with David Boyd and Greg Martin.

Zero density estimates for the zeros of the Riemann zeta function

An important tool in the analytic investigation of the distribution of primes consists in estimates for the density of zeros of the Riemann zeta function in the critical strip $0 < x < 1$.

We denote $N(a, T)$ the number of such zeros in the region $\{a < x < 1 \mid 0 < y < T\}$. It is expected that the zeros close to the 1-line are rare (and thus that $N(a, T)$ decreases with a). Great efforts have been made to establish asymptotic results of the form

$$N(a, T) \ll T^{c(a)(1-a)} (\log T)^A,$$

where $c(a)$ and A are positive. However, there are very few explicit bounds for $N(a, T)$.

In this talk, we will present the following result together with the ideas for its proof:

$$N(a, T) < c_1(a)T + c_2(a) \log T - c_3(a),$$

where each c_i is explicit and positive.

Brandon Fodden (Math and CS, U of Lethbridge)

Jan 30, 2012

Hilbert's Tenth Problem

Hilbert's Tenth Problem asks for an algorithm which can determine if an arbitrary Diophantine equation (with integral coefficients) has solutions. In 1970 Yuri Matiyasevich, building on the work of Martin Davis, Julia Robinson and Hilary Putnam, showed that no such algorithm may exist. In this talk, we give an outline of a proof of this, and discuss some applications and related problems. No specialist knowledge is assumed and everyone is welcome.

PDF slides of the talk are available at

Feb 13, 2012

Maass forms

This is an introductory talk on Maass forms for $SL(2, \mathbb{Z})$. These objects were first studied by H. Maass in 1949. They appeared as non-holomorphic analogues of modular forms. Maass called them waveforms. We follow the presentation given in Sections 1.6 and 1.9 of Bump's book (Automorphic Forms and Representations)

Yuri Matiyasevich (Steklov Institute, Russia)

Feb 27, 2012

New conjectures about zeros of Riemann's zeta function

In <http://logic.pdmi.ras.ru/~yumat/personaljournal/artlessmethod/artlessmethod.php> the speaker described a surprising method for (approximate) calculation of the zeros of Riemann's zeta function using terms of the divergent Dirichlet series. In the talk this method will be presented together with some heuristic "hints" explaining why the divergence of the series doesn't spoil its use. Several conjectures about the zeros of Riemann's zeta function will be stated including supposed new relationship between them and the prime numbers.

Ted Dobson (Mississippi State University)

Feb 29, 2012

Groups that are transitive on all partitions of a finite set

Let ℓ_1, \dots, ℓ_r be positive integers whose sum is n . Let K_1, \dots, K_r be subsets of the n -element set $[n] = \{1, \dots, n\}$ such that these sets form a partition P of $[n]$ and $|K_i| = \ell_i$. We say that $[\ell_1, \dots, \ell_r]$ is the *shape* of P . Let \mathcal{P} be the set of all partitions of $[n]$ with shape $[\ell_1, \dots, \ell_r]$. We determine all subgroups of S_n that are transitive on \mathcal{P} for every possible shape $[\ell_1, \dots, \ell_r]$, as well as determine all subgroups of S_n that are transitive on the set of all ordered partitions of every possible shape. As an application, we determine which Johnson graphs are isomorphic to Cayley graphs. This is joint work with Aleksander Malnič.

Two approaches to compute $GL(3)$ automorphic forms

In this talk we present methods using the functional equation and Voronoi summation formula to compute the Casimir eigenvalues and Hecke eigenvalues of certain automorphic forms on $GL(3)$.

Timothy Trudgian (Math and CS, U of Lethbridge)

Mar 12, 2012

Some mathematics in voting

Many countries employ different voting systems, each with its own advantages and disadvantages. In Australia the 'preferential' voting system is used: candidates are numbered 1 through to n . One disadvantage is a theoretical occurrence of non-monotonicity: essentially candidates can be ranked more highly and yet they, almost paradoxically, perform more poorly. The debate about the likelihood of such a paradox has influenced recent decisions (notably in the UK) about whether a particular voting system should be adopted. I will try to sketch a mathematical approach to this problem.

Joy Morris (Math and CS, U of Lethbridge)

Mar 19, 2012

The probabilistic method

Paul Erdős is well-known for the number and breadth of his publications. His most significant contributions to combinatorics involved using the “probabilistic method:” proving that various objects must exist by developing a probability model and proving that the probability of finding such an object is strictly greater than 0. I will introduce the probabilistic method, and work through examples of several theorems that can be proved using this method.

Soroosh Yazdani (Math and CS, U of Lethbridge)

Mar 26, 2012

Death of synthetic geometry

Since antiquity people have been intrigued by problems like the “problems of Apollonius:” construct a circle tangent to three given circles. This specific problem can be solved using compass and straight edge. Jacob Steiner in 1848 pointed out that when the circles are replaced by arbitrary conics, these problems become more involved. For one thing it should take 5 conics, rather than 3, to determine the unknown conic. Furthermore, the five conic rarely determine a single conic, which raises the question, known as the Steiner problem, of how many conics are tangent to 5 given conics. Steiner conjectured that there are $6^5 = 7776$ conics, but did not elaborate much on this conjecture. This was proved by Johann Bischoff in 1859, but it was soon realized that this is not the right answer to the question.

In this talk I will explain how do we get this answer, why this is not the right answer, how to get the right answer, and why this is an example of a problem responsible for killing synthetic geometry, and for that matter, what do I mean by synthetic geometry.

Dave Morris (Math and CS, U of Lethbridge)

Apr 2, 2012

Strictly convex norms on amenable groups

It is obvious that the usual Euclidean norm is strictly convex, by which we mean that, for all x and all nonzero y , either $\|x + y\| > \|x\|$, or $\|x - y\| > \|x\|$. We will discuss the existence of such a norm on an abstract (countable) group G . A sufficient condition is the existence of a faithful action of G by orientation-preserving homeomorphisms of the real line. No examples are known to show that this is not a necessary condition, and we will combine some elementary measure theory and dynamics with the theory of orderable groups to show that the condition is indeed necessary if G is amenable. This is joint work with Peter Linnell of Virginia Tech.

Michael Coons (University of Waterloo, Ontario)

Apr 10, 2012

Diophantine approximation of Mahler numbers

Let $F(x) \in \mathbb{Z}[[x]]$ be a Mahler function; that is, there exist positive integers $k \geq 2$ and $d \geq 1$ and polynomials $a_0(x), \dots, a_d(x) \in \mathbb{Z}[x]$ with $a_0(x)a_d(x) \neq 0$ such that

$$\sum_{i=0}^d a_i(x)F(x^{k^i}) = 0.$$

Let ξ be a real number. The irrationality exponent $\mu(\xi)$ of ξ is defined as the supremum of the set of real numbers μ such that the inequality $|\xi p/q| < q^{-\mu}$ has infinitely many solutions $(p, q) \in \mathbb{Z} \times \mathbb{N}$. Last year (in a talk at the University of Lethbridge), I showed that the sum of the reciprocals of the Fermat numbers (which is a special value of a Mahler function) has irrationality exponent 2 and I conjectured that all reasonable special values of Mahler functions should have finite irrationality exponent. In this talk, I will present some of the history of Mahler functions and Diophantine approximation with a view towards the proof of the above-mentioned conjecture.

Paul Buckingham (University of Alberta)

Apr 16, 2012

p -adic L -functions, and derivatives of Artin L -functions at $s = 0$

p -adic L -functions are traditionally obtained from the more classical Artin L -functions by interpolating their values at negative integers. Iwasawa gave an alternative construction which, surprisingly, involves only values at $s = 0$. We will discuss a relatively new object defined in terms of derivatives at $s = 0$, instead of simply values, which appears to extend Iwasawa's construction to a potentially new kind of p -adic L -function. The talk will assume no prior knowledge of p -adic numbers.

From Pythagoras to Beal?

In this talk I will look at some of Diophantine equations of the form $x^p + y^q = z^r$. The oldest of this equation studied is probably when $p = q = r = 2$ (Pythagorean triples), and probably the most famous one is when $p = q = r > 2$ (Fermat's last theorem). However, many other variations exist, and in this talk I will present what is known about them, and what is believed to be true.

Joy Morris (Math and CS, U of Lethbridge)

Sept 28, 2011

Generalised n -gons with symmetry conditions

A generalised n -gon is an incidence structure whose bipartite incidence graph has diameter n and girth $2n$. Many of the known examples of generalised n -gons are highly symmetric, and in fact arise naturally from particular group actions.

I will give an overview of some of the things that are known about symmetries of generalised n -gons that we hope are leading toward classification of these objects, or at least to understanding the symmetry that they can have. My contributions to this problem are based on joint work with John Bamberg, Michael Giudici, Gordon Royle and Pablo Spiga of the University of Western Australia, done during my study leave.

Nathan Ng (Math and CS, U of Lethbridge)

Oct 5, 2011

What is a modular form?

Modular forms play an important role in many branches of mathematics including number theory, arithmetic geometry, representation theory, and even theoretical physics. In this talk I will give a general introduction to modular forms and I will explain some of their fundamental properties.

Nathan Ng (Math and CS, U of Lethbridge)

Oct 12, 2011

Simple zeros of modular L -functions

An old problem in analytic number theory is to show that an L -function possess simple zeros. Thanks to work of Levinson and Bauer, it is known that any degree one L -function has many simple zeros. For degree two L -functions there are fewer results known. Recently, the speaker and Milinovich have established a number of results concerning simple zeros of modular L -functions.

Timothy Trudgian (Math and CS, U of Lethbridge)

Oct 19, 2011

One way to improve Ingham's theorem

One can conjecture the size of a certain arithmetic function: such a conjecture often implies the Riemann hypothesis and, courtesy of Ingham's theorem, that there are infinitely many zeroes the imaginary parts of which are linearly dependent. This is indeed bitter-sweet since, if one were keen to place a wager, one might venture to say that no zeroes are linearly dependent. Very little work has been done to find, computationally, 'near-zero' linear combinations of zeroes. The topic of this paper is to discuss what has been done by Bateman and co. in 'Linear relations connecting the imaginary parts of the zeros of the zeta function'.

Hadi Kharaghani (Math and CS, U of Lethbridge)

Oct 26, 2011

Mutually unbiased Hadamard matrices

Two unit Hadamard matrices H, K of order n are called unbiased, if $HK^* = \sqrt{n}L$, where L is a unit Hadamard matrix. Time permitting, I will do all or part of the following:

- If there are m mutually unbiased unit (real) Hadamard matrices of order n , then $m \leq n$ ($m \leq n/2$).
- The above upper bound is sharp for n a prime power.
- Discuss the literature for composite orders n .
- Talk about mutually unbiased real Hadamard matrices and their applications to association schemes.

Nathan Ng (Math and CS, U of Lethbridge)

Nov 2, 2011

A theorem of Frobenius

Consider the irreducible polynomial $f(x) = x^3 - x - 1$. Let p be a prime and consider this as a polynomial over the finite field of p elements. Over this field the polynomial is either irreducible, splits into three linear factors, or splits into a linear factor and a quadratic factor. Frobenius proved a theorem which asserts that these 3 cases occur with frequencies: $1/3$, $1/6$, and $1/2$. Why do these fractions occur? The answer is related to the fact that the Galois group of f is the symmetric group of 3 letters. Moreover, he considered how an irreducible polynomial factors when reduced modulo p . In this talk I will explain Frobenius' theorem. This seminar will be accessible to undergraduate students who have taken Math 3400 (Group and Rings).

Dirichlet's theorem and an application to the zeta-function

Suppose one has managed to bound a certain complex-valued function, $f(z)$ say, by another function $g(z)$. How could one show that the bound $g(z)$ is 'as good as it gets'? The study of so-called Omega-theorems is designed to answer this question. Dirichlet's theorem (which is not much more complicated than the statement that if $k + 1$ students need to sit on k chairs then at least two of them must sit in the same chair) provides a good insight into Omega-theorems: in particular one may use Dirichlet's theorem to show that some bounds for the growth of the zeta-function are the best possible.

Nov 16, 2011

Introduction to elliptic curves

In this talk we give a brief introduction to elliptic curves. We start by describing what they are, where they came from, and why number theorists are obsessed by them.

Amir Akbary (Math and CS, U of Lethbridge)

Nov 23, 2011

On a theorem of Jordan

We give an exposition of a paper of Jean-Pierre Serre with the same title (Bulletin of AMS, Volume 40 (2003), 429–440). Its abstract reads as follows: “The theorem of Jordan which I want to discuss here dates from 1872. It is an elementary result on finite groups of permutations. I shall first present its translations in Number Theory and Topology.”

Dave Morris (Math and CS, U of Lethbridge)

Nov 30, 2011

Hamiltonian checkerboards

Place a checker on some square of an m -by- n rectangular checkerboard. Asking whether the checker can tour the board, visiting all of the squares without repeats, is the same as asking whether a certain graph has a hamiltonian path (or hamiltonian cycle). The question becomes more interesting if we allow the checker to step off the edge of the board. This modification leads to numerous open problems, and also to connections with ideas from elementary topology and group theory. Some of the problems may be easy, but many have resisted attack for 30 years. No advanced mathematical training will be needed to understand most of this talk.

Dave Morris (Math and CS, U of Lethbridge)

Dec 7, 2011

How to make infinitely large numbers from two-player games

We will talk about certain strategy games, in which the moves alternate between two players. Chess, checkers, and Go are some of the games we could discuss, but, to keep things simple, we will stick to easier examples. John H. Conway discovered that analyzing who will win from a given starting position has some very interesting consequences. In particular, we will see how to add two games (or subtract them, or multiply them), and we will encounter numbers that are infinitely large. No advanced mathematical training will be needed to understand most of this talk, but it would be helpful to have heard of “Dedekind cuts”.

The main talk will be preceded by a short explanation of “Zero-Knowledge Proofs.” These allow you to convince someone you know how to prove a theorem, without giving them any information at all about the proof (except how long it is).

Sept 29, 2010

Gram's Law and the zeroes of the Riemann zeta-function (I)

That all the complex zeroes of the zeta-function lie on the critical line is the Riemann Hypothesis. Regrettably, the margin for this abstract is too narrow to write down a proof. The first 15 zeroes on the critical line were found by Gram in 1903. As a general rule of thumb, he proposed what is now called 'Gram's Law', a phenomenon by the use of which one can locate zeroes on the critical line. All subsequent searches for zeroes on the critical line use this method, in some form or another. In this seminar I shall summarise the theory one requires to state Gram's Law, as well as providing motivation for why it might be true significantly often.

Tim Trudgian (Math and CS, U of Lethbridge)

Oct 6, 2010

Gram's Law and the zeroes of the Riemann zeta-function (II)

With Gram's Law clearly defined, I shall develop the necessary theory to see whether it fails or holds in a positive proportion of cases. Several versions of Gram's Law hold and fail at this frequency, and this was my doctoral research at Oxford. Motivation from random-matrix theory will perhaps indicate the true rate of success and failure of Gram's Law.

Nathan Ng (Math and CS, U of Lethbridge)

Oct 27, 2010

Nonzero values of Dirichlet L -functions in vertical arithmetic progressions

An open question in analytic number theory is:

How do the zeros of a Dirichlet L -function behave in the critical strip?

One might wonder whether the zeros bunch up or are they very well-spaced.

In particular, is it possible for the zeros to lie in an arithmetic progression?

In joint work with Greg Martin, we show that many terms of an arithmetic progression are not zeros of a fixed Dirichlet L -function.

Amir Akbary (Math and CS, U of Lethbridge)

Nov 24, 2010

Uniform distribution of zeros of the Riemann zeta function

We explain the Weyl criterion for the uniform distribution mod 1 of a sequence of real numbers.

As an application of this criterion we describe a theorem of Hlawka on the uniform distribution mod 1 of the imaginary parts of the zeros of the Riemann zeta function.

Dave Morris (Math and CS, U of Lethbridge)

Dec 8, 2010

Reconstruction from vertex-switching

The Reconstruction Conjecture is a famous unsolved problem in graph theory. We will discuss a related problem that was partially solved by Richard Stanley in 1985. He used the Radon Transform, which is a technique that originated in analysis, and is the mathematical basis of modern CAT scans (used in medical diagnostics).

Linear combinations of the zeros of the zeta function

The linear independence conjecture asserts that the imaginary ordinates of the zeros of the zeta function are linearly independent over the rationals. This conjecture has played an important role in several classical problems in analytic number theory including the Mertens conjecture and the Shanks-Renyi prime number race game. I will discuss the history of this conjecture and some preliminary results concerning linear combinations of the zeros of zeta function. This is joint work with Greg Martin.

Vorrapan Chandee (Stanford University, California)

Mar 4, 2010

On the correlation of shifted values of the Riemann zeta function.

In 2007, assuming the Riemann Hypothesis (RH), Soundararajan proved that the $2k$ -th moments of the Riemann zeta function on the critical line is bounded by $T(\log T)^{k^2+\epsilon}$ for every k positive real number and every $\epsilon > 0$. In this talk I will generalize his methods to find upper bounds for shifted moments. Also I will sketch the proof how we derive their lower bounds and conjecture asymptotic formulas based on Random matrix model, which is analogous to Keating and Snaith's work. These upper and lower bounds suggest that the correlation of $|\zeta(1/2 + it + i\alpha_1)|$ and $|\zeta(1/2 + it + i\alpha_2)|$ transition at $|\alpha_1 - \alpha_2|$ is around $1/\log T$. In particular these distribution appear independent when $|\alpha_1 - \alpha_2|$ is much larger than $1/\log T$.

Micah Milinovich (University of Mississippi)

Mar 17, 2010

Central values of derivatives of Dirichlet L -functions

It is believed (a conjecture usually attributed to S. Chowla) that no primitive Dirichlet L -function vanishes at the center of the critical strip $s = 1/2$. This problem is still open. The best partial is due to H. Iwaniec and P. Sarnak who have shown that at least a third of the Dirichlet L -functions, to a large modulus q , do not vanish at the central point. I will describe how to modify their method and show that, for k and q large, almost all of the values of the k -th derivatives of primitive Dirichlet L -functions (mod q) are nonzero at $s = 1/2$. Our result compliments earlier work of P. Michel and J. VanderKam who considered a similar problem. This is joint work with Hung M. Bui.

Habiba Kadiri (Math and CS, U of Lethbridge)

Mar 31, 2010

Explicit bounds for some prime counting functions.

A prime counting function assigns a weight to each prime number. For example $\pi(x)$ counts exactly the number of prime numbers less than an arbitrarily large number x . It was conjectured by Gauss that $\pi(x)$ is of the size $\frac{x}{\log x}$ as x grows larger. In 1859, Riemann proposed a formula relating prime counting functions to the zeros of a complex function (now called the Riemann Zeta function). This innovative approach allowed Hadamard and de la Vallée Poussin to establish the Prime Number Theorem:

$$\pi(x) \sim \frac{x}{\log x}.$$

An explicit bound for this error term has been successively investigated by Rosser, Schoenfeld, and more recently by Dusart. I will start the talk by explaining their method and I will then present a new approach investigated last summer together with Laura Faber, Allysa Lumley and Nathan Ng.

Habiba Kadiri (Math and CS, U of Lethbridge)

Apr 7, 2010

Explicit bounds for some prime counting functions (II)

This talk is a continuation of last week's talk. I will explain how to obtain lower and upper bounds for the prime counting function $\psi(x)$. The proof uses smooth functions and the theory of Mellin transforms. We will also see how the previous method of Rosser and Schoenfeld is reinterpreted through this method.

Arithmetic dynamics

Starting from a fundamental question regarding roots of unity we present a generalization of the classical Manin-Mumford conjecture in the context of algebraic dynamics.

Brandon Fodden (Math and CS, U of Lethbridge)

Oct 16, 2009

An explicit inequality equivalence of the generalized Riemann hypothesis for a member of the Selberg class

Given a member F of the Selberg class, we find a property P of the natural numbers such that the generalized Riemann hypothesis holds for F if and only if P holds for all natural numbers. P is given as an explicit inequality. If one can show that P is a decidable property, then the generalized Riemann hypothesis for F is equivalent to the unsolvability of a particular Diophantine equation. We discuss variants of P for which proving decidability is more practical. Finally, we apply this result to L -functions related to elliptic curves.

Amir Akbary (Math and CS, U of Lethbridge)

Oct 28, 2009

Analytic problems for elliptic curves (I): Titchmarsh Divisor Problem

Titchmarsh Divisor Problem concerns the asymptotic behavior of the sum (on primes up to x) of the number of divisors of shifted primes. In 1930 Titchmarsh studied this problem and conjectured an asymptotic formula for such a sum. In 1961 Linnik proved that Titchmarsh's conjecture is true.

In this talk we will review the results given in the original paper of Titchmarsh. Our goal here is to describe an analogue of the Titchmarsh Divisor Problem in the context of elliptic curves.

Amir Akbary (Math and CS, U of Lethbridge)

Nov 4, 2009

Analytic problems for elliptic curves (II): an elliptic analogue of the Titchmarsh Divisor Problem

We continue our discussion on the Titchmarsh Divisor Problem. Recall that this problem concerns the asymptotic behavior of the sum

$$\sum_{\substack{p \leq x \\ p \text{ prime}}} \tau(p-1)$$

as $x \rightarrow \infty$, where $\tau(p-1)$ is the number of divisors of $p-1$.

Our goal is to describe an analogue of this problem in the context of elliptic curves.

Nathan Ng (Math and CS, U of Lethbridge)

Nov 18, 2009

A brief history of the Riemann Hypothesis

In 1859, Riemann introduced the zeta function to the theory of prime numbers. Riemann proved some basic properties regarding the behaviour of this function: functional equation, approximate functional equation, number of zeros in a box, and explicit formula. Moreover, he introduced a profound conjecture, the Riemann hypothesis, which concerns the location of zeros of the zeta function. In this talk I will discuss Riemann's conjecture and its great influence on analytic number theory.

Howard Cheng (Math and CS, U of Lethbridge)

Nov 27, 2009

Time- and space-efficient computation of hypergeometric constants

Hypergeometric series are infinite series of the form

$$\sum_{n=0}^{\infty} a(n) \prod_{i=0}^{n-1} \frac{p(i)}{q(i)}$$

where a , p , and q are polynomials with integer coefficients. Many elementary functions evaluated at rational points may be approximated to high precision (millions of digits) by using hypergeometric series with a technique commonly known as “binary splitting.” Furthermore, well-known constants such as π and $\zeta(3)$ can also be evaluated in this manner.

Although the binary splitting method is relatively efficient in terms of time, it is not optimal in terms of the amount of space (memory) used. In this talk, we look at the development of an algorithm that is space-efficient—it uses only $O(N)$ extra space where N is the number of digits desired. Its time complexity is the same as binary splitting but is faster in practice. Elementary properties of integer factorization and prime numbers are used to obtain the resulting algorithm. To the best of my knowledge, this is also the fastest algorithm for this type of calculations.

Dave Morris (Math and CS, U of Lethbridge)

Dec 2, 2009

Some arithmetic groups that cannot act on the line

It is known that finite-index subgroups of the arithmetic group $SL(3, \mathbb{Z})$ have no interesting actions on the real line. This naturally led to the conjecture that most other arithmetic groups (of higher real rank) also cannot act on the line (except by linear-fractional transformations). This problem remains open, but my joint work with Lucy Lifschitz (University of Oklahoma) and Vladimir Chernousov (University of Alberta) has verified the conjecture for many examples. The proofs are based on the fact, proved by D. Carter, G. Keller, and E. Paige, that if A is the ring of integers of an algebraic number field, and A has infinitely many units, then every element of $SL(2, A)$ is a product of a bounded number of elementary matrices.

Habiba Kadiri (Math and CS, U of Lethbridge)
The Ihara Zeta function of graphs

Jan 14, 2009

In this talk, I will give an introduction to the Ihara Zeta function of graphs, which has analogous behavior to the Riemann Zeta function. For example, we will discuss its analytical properties, the explicit formula, the Riemann Hypothesis and the Graph Prime Number Theorem.

This talk is accessible to students.

Habiba Kadiri (Math and CS, U of Lethbridge)
About the distribution of the eigenvalues of Ramanujan's graphs

Jan 21, 2009

In the last lecture, we discovered the notion of arithmetic for graphs and how the Ihara Zeta function was used to count the number of paths and prime paths of arbitrarily large length. This type of relation is analogous to the relation between the distribution of prime numbers and the location of the zeros of the Riemann Zeta function.

This lecture is a follow up to the previous lecture. I will focus on some particular regular graphs, called Ramanujan graphs. These graphs appear in various domains of mathematics and computer science. I will discuss the distribution of the eigenvalues for Ramanujan graphs, the Riemann Hypothesis for graphs and compare it to the case of the classical Riemann Zeta function. If time permits, I will also discuss the problem of the distribution of the spacings of the zeros.

Amir Akbary (Math and CS, U of Lethbridge)
Ramanujan graphs

Feb 11, 2009

A Ramanujan graph is a connected regular graph whose non-trivial eigenvalues are relatively small in absolute value. This talk introduces these graphs and describes some basic constructions of them.

The talk will be accessible to people familiar with basic elements of graph theory.

Amir Akbary and Dave Morris (Math and CS, U of Lethbridge)
Expander graphs

Feb 25, 2009

This talk will introduce the class of expander graphs, and describe some of their basic properties. We will start the seminar with some applications of Ramanujan graphs, which are a special case.

The talk will be accessible to people familiar with basic elements of graph theory.

Dave Morris (Math and CS, U of Lethbridge)

Mar 4, 2009

More on expander graphs

This talk will have three parts: a proof that random k -regular graphs are very likely to be expanders, a discussion of the eigenvalues of the adjacency matrix of an expander graph, and a brief explanation of Margulis' explicit construction of expander graphs.

Kaneenika Sinha (University of Alberta)

Mar 18, 2009

A trace formula for Hecke operators on spaces of newforms

Fourier coefficients of some appropriately chosen modular forms can be interpreted as eigenvalues of Hecke operators. We derive a trace formula for Hecke operators acting on spaces of newforms of given level and weight. This explicit formula can be applied to study the distribution of Fourier coefficients of newforms. We will also derive arithmetic information about newparts of Jacobians of modular forms.

Brandon Fodden (Math and CS, U of Lethbridge) Sept 10, 2008
A lower bound for fractional moments of certain L -functions

We extend the method of Heath-Brown to find a lower bound for the fractional moments of a certain class of L -functions.

Dragos Ghioca (Math and CS, U of Lethbridge) Sept 17, 2008
Algebraic dynamics

The classical Mordell-Lang conjecture (proven by Faltings and Vojta) describes the intersection between a finitely generated subgroup of a semiabelian variety defined over the field of complex numbers with a subvariety V of G . We may view this subgroup of G as the image of 0 under the action of a finitely generated semigroup S of automorphisms of G (each automorphism being a translation). We present extensions of the Mordell-Lang conjecture in which S is any finitely generated semigroup of endomorphisms of G .

Amir Akbary (Math and CS, U of Lethbridge) Sept 24, 2008
Rankin-Selberg Convolutions

We describe how the study of the analytic properties of the convolution of the Dirichlet series leads to the results on the size of the coefficients of the Dirichlet series.

Nathan Ng (Math and CS, U of Lethbridge) Oct 1, 2008
Non-vanishing of L -functions and application to a Fermat equation

In recent years, a popular research topic in analytic number theory has been the non-vanishing of L -functions. In this talk I will discuss some non-vanishing results which imply the Fermat equation $A^4 + B^2 = C^p$ for p a prime larger than 5 has no non-trivial solutions.

Nathan Ng (Math and CS, U of Lethbridge) Oct 22, 2008
The Mobius function summed over short intervals

The Central Limit Theorem in probability determines that a sum of independent identically distributed random variables is normally distributed. A number theoretic model for a sequence of such random variables is the Mobius function. In this talk we discuss the distribution of the sum of the Mobius function in short and long intervals. We will see that in short intervals the Mobius function behaves like a sum of independent random variables. However, over longer intervals its behaviour depends on the zeros of the zeta function.

Chantal David (Concordia University, Quebec)

Nov 10, 2008

Almost prime orders of elliptic curves over finite fields

Let E be an elliptic curve over the rationals. A conjecture of Neal Koblitz predicts an exact asymptotic for the number of primes p such that the order of E over the finite field with p elements is prime. This conjecture is still open. Using sieve techniques, one can find a lot of primes p such that the order $p + 1 - a_p(E)$ is almost prime. The best result that one may hope to achieve by sieve techniques was obtained by Iwaniec and Jimenez Urroz for complex multiplication curves using Chen's sieve. They showed that there are infinitely many primes p such that $p + 1 - a_p(E) = P_2$, where $n = P_k$ means that the integer n has at most k prime factors. For elliptic curves without complex multiplication, it is not known how to apply the switching principle of Chen's sieve to get such a result.

For curves without complex multiplication, we show that there are many primes p such that $p + 1 - a_p(E) = P_8$ with an explicit lower bound (in terms of the constant $C(E)$ of Koblitz's conjecture), using Greaves' sieve and under the GRH. This improves previous work of Steuding and Weng. One can also show that there are many primes such that $p + 1 - a_p(E)$ has at most 6 *distinct* prime factors, but still cannot improve the number of (not necessarily distinct) primes from 8 to 6. This surprising result is related to the difficulty of sieving square-free numbers in the sequence $p + 1 - a_p(E)$.

This is joint work with Jie Wu (CNRS, Institut Elie-Cartan, Nancy).

Harald Helfgott (University of Bristol, England)

Nov 21, 2008

Escape and incidence: their role in growth in groups

There is, so far, one tool that geometric group theory (largely on infinite groups) and recent work on non-commutative group combinatorics (largely on finite groups) have in common: the idea of escape.

After a brief discussion of what escape is and how it can be used, we shall pass to the possibility of restating much of "additive combinatorics" as the combinatorics of an abstract projective plane. There is a basic statement in the latter that does not seem to have a clear analogue in classical additive combinatorics; we shall see how the main idea of the proof is, again, escape.

Hadi Kharaghani (Math and CS, U of Lethbridge)

Nov 26, 2008

On mutually unbiased Hadamard matrices

Two Hadamard matrices H and K of order n are called *unbiased* if $HK^t = \sqrt{n}L$, where L is a Hadamard matrix of order n . Mutually unbiased Hadamard matrices have applications in quantum measurement, quantum cryptography and design theory. I will try to give a simple survey talk on the the existence, structure and applications of these matrices.

This talk will be accessible to the senior undergraduate mathematics students.

Pablo Spiga (University of Padova, Italy)

Dec 3, 2008

Synchronization and homomorphisms

An automaton is a machine which can be in any of a set of internal states which cannot be directly observed. A synchronizing automaton is an automaton admitting a sequence of transitions which take the automaton from any state into a known state. In this talk we present some recent connections between synchronizing automata, permutation groups and graph homomorphisms. All relevant definitions would be given during the talk.

Dragos Ghioca (Math and CS, U of Lethbridge)
Skolem-Mahler-Lech theorem

Jan10, 2008

We present an old result for linear recurrence sequences whose proof relies on p -adic analysis. Based on it we derive an interesting result for automorphisms of the affine space.

Nathan Ng (Math and CS, U of Lethbridge)
Lower bounds for moments of L -functions

Jan 24, 2008

Hardy and Littlewood initiated the study of high moments of the Riemann zeta function. They were initially interested in this problem because of its connection to the Lindelof hypothesis. In recent years, the moments of central values of families of L -functions have attracted much attention. In this talk I will explain a recent method of Rudnick and Soundararajan which establishes lower bounds for moments of L -functions of the correct order or magnitude.

Amir Akbary (Math and CS, U of Lethbridge)
On the reduction mod p of a rational point of an elliptic curve

Jan 31, 2008

Let E be an elliptic curve over \mathbb{Q} . For any prime p of good reduction, let E_p be the elliptic curve over the finite field \mathbf{F}_p obtained by reducing E modulo p . We investigate that for a point of infinite order in the Mordell group $E(\mathbb{Q})$, how the order of the reduction of this point mod p varies as p goes to infinity. We study this problem by comparison with reduction of integers mod p .

Nathan Ng (Math and CS, U of Lethbridge)
Upper bounds for moments of the Riemann zeta function

Feb 7, 2008

I will explain a recent method of Soundararajan that proves an upper bound for moments of the Riemann zeta function which is nearly as sharp as the expected order of magnitude. This technique assumes the Riemann hypothesis and relies on obtaining an upper bound for the frequency of values for which the zeta function is large on the critical line.

John Irving (Saint Mary's University, Nova Scotia)
Lattice paths under a shifting boundary

Feb 14, 2008

The generalized ballot theorem gives a well-known formula for the number of lattice paths in the first quadrant lying weakly under the line $x = ay$, where a is an arbitrary positive integer. While there is almost certainly no simple formula for the number of paths under an arbitrary piecewise linear boundary, we show that nice enumerative results are available if we allow for cyclic shifts of such a general boundaries. A refinement of this result allows for the counting of paths with a specified number of corners, and we also examine paths dominated by periodic boundaries. This is joint work with A. Rattan.

Nathan Ng (Math and CS, U of Lethbridge)

Feb 28, 2008

Upper bounds of the Riemann zeta function

Hadamard and Weierstrass proved a product formula for entire functions of order one. This factorization theorem leads to a formula for the logarithmic derivative of the zeta function in terms of the zeros of the zeta function. I will explain how such formulae can be applied to obtain upper bounds for the Riemann zeta function on the critical line. This talk is based on recent work of Soundararajan.

Matthew Greenberg (University of Calgary)

Mar 13, 2008

Modular forms, Stark units and Heegner points

In this talk, we will discuss constructions and conjectures concerning units in rings of algebraic integers and algebraic points on elliptic curves over number fields. Modular forms, in various guises, are the key ingredients in all known systematic constructions of such objects.

Brandon Fodden (Math and CS, U of Lethbridge)

Mar 20, 2008

Fractional moments of the Riemann zeta function

We discuss the Heath-Brown method to find upper and lower bounds for the fractional moment of the Riemann zeta function for s with real part $1/2$.

Mar 27, 2008

The energy of matrices

Let M be an m by n matrix, $m \leq n$. Let $\lambda_i, i = 1, 2, \dots, m$ be the eigenvalues of the matrix MM^t . Motivated by an application in theoretical chemistry, Gutman defined the energy of M to be the sum of the square roots of λ_i 's. The $(0, 1)$ -matrices attaining maximum energy will be discussed.

Habiba Kadiri (Math and CS, U of Lethbridge)

Apr 3, 2008

A bound for the least prime ideal in the Chebotarev density problem.

A classical theorem due to Linnik gives a bound for the least prime number in an arithmetic progression. Lagarias, Montgomery and Odlyzko gave a generalization of this result to any number field. Their proof relies on some results about the distribution of the zeros of the Dedekind Zeta function (zero free regions, Deuring Heilbronn phenomenon). In this talk, I will present some new results about these zeros. As a consequence, we are able to prove an effective version of the theorem of Lagarias et al.

Harald Helfgott (University of Bristol, England)
Growth in SL_3

Apr 17, 2008

Let K be \mathbb{R} , \mathbb{C} or a $\mathbb{Z}/p\mathbb{Z}$. Let $G = SL_2(K)$. Not long ago, I proved the following theorem: for every subset A of G that is not contained in a proper subgroup, the set AAA is much larger than A . A generalization to groups of higher rank was desired by many, but seemed hard to obtain. I have obtained a generalization to $SL_3(K)$. The role of both linearity and the group structure of G should now be clearer than they were at first. Bourgain, Gamburd and Sarnak derived various consequences on expander graphs from my SL_2 result; analogous consequences should follow in the case of SL_3 .

Nathan Jones (Centre de Recherches Mathématiques, Montreal, Quebec)
A refined version of the Lang-Trotter conjecture

May 9, 2008

Let E be an elliptic curve defined over the rational numbers and r a fixed integer. Using a probabilistic model consistent with the Chebotarev density theorem for the division fields of E and the Sato-Tate distribution, Lang and Trotter conjectured an asymptotic formula for the number of primes up to x which have Frobenius trace equal to r . However, when one sums the main term in their asymptotic over r in a fixed residue class modulo q , one does not recover the main term in the Chebotarev theorem for the q -th division field, but rather $8/\pi$ times the main term.

In this talk, I will state a refinement of the Lang-Trotter conjecture and demonstrate consistency of this refinement with the Chebotarev Theorem for a fixed division field. This is based on joint work with S. Baier.

Diophantine equations and the generalized Riemann hypothesis

Sept 26, 2007

We show that the statement “for all number fields K , the generalized Riemann hypothesis for K holds” is equivalent to a statement of the form “for all natural numbers n , property P holds” where P is a decidable property of the natural numbers (that is, there is an algorithm which will tell if P holds for an arbitrary natural number in finitely many steps). This in turn implies that the original statement is equivalent to the unsolvability of a particular Diophantine equation in the integers.

Polynomial dynamics in number theory

Oct 10, 2007

We study orbits of complex polynomials from the point of view of arithmetic geometry. In particular we show that if two nonlinear complex polynomials have orbits with infinite intersection, then the polynomials have a common iterate.

Nathan Ng (Math and CS, U of Lethbridge)
Chebyshev's Bias, Galois groups, and L -functions

Oct 26, 2007

Chebyshev observed the strange phenomenon that there appear to be more primes congruent to three modulo four than to one modulo four. This is counterintuitive since one expects that there are an equal number of primes congruent to three modulo four than to one modulo four. In this talk, I will explain this phenomenon known as “Chebyshev's bias” and I will discuss generalizations. For example, consider the polynomial $x^3 - x - 1$. If we consider this polynomial modulo p a prime, this polynomial is either irreducible, splits into a linear factor and a quadratic factor, or splits into three linear factors. I will explain which of these cases occurs the most frequently and I will explain why the “bias” arises.

About Vinogradov's bound for the three primes Goldbach's conjecture

Can any odd number greater than 5 be written as a sum of 3 primes? In 1922, Hardy and Littlewood were the first to give a substantial answer to this question: using their Circle Method, they proved that, under the condition of the Generalized Riemann Hypothesis, it was true for sufficiently large integers.

Fifteen years later, Vinogradov removed completely this hypothesis. His theorem remains one of the strongest results in the direction of Goldbach's conjecture. In this lecture, we will go through Vinogradov's proof, and understand how the distribution of the zeros of the Dirichlet L -functions enter into play.

Lattice path bijections

Two opponents play $2n$ head to head games, and each player wins a total of n games. In how many ways can this be done, if the second player never has more wins than her opponent?

This puzzle can be solved with lattice paths: paths in the plane from the point $(0, 0)$ to (n, n) , where each step in the path is in the direction $(1, 0)$ or $(0, 1)$. We survey enumeration results for various modifications of lattice paths. Classical bijections and a search for a new bijection are also discussed.

On circular units and the class group of an abelian field

The aim of this talk is to show that circular units can be used to study the class group of an abelian field. At the beginning we recall the definition and basic properties of the group of circular units of an abelian number field (explicit generators, finite index in the full group of units, Sinnott's formula containing the class number).

Then we show a concrete application: having a compositum K of real quadratic fields unramified at 2, we derive a lower bound for the divisibility of the class number of K by a power of 2.

We also explain that circular units can be used to obtain an information concerning the Galois module structure of the class group: For an abelian field K and a prime p , two Galois modules appear here naturally, namely the p -th part of the group of all units modulo the subgroup of circular units and the p -th part of the class group. Thaine's theorem states that any annihilator of the former module is an annihilator of the latter one, provided p is odd and relatively prime to the degree of the field.

Finally a joint result with C. Greither concerning the p -th part of the class group of cyclic fields of p -power degree will be explained.

Sharp upper bounds for divisor sums

We describe an algorithm that provides explicit upper bounds for a certain arithmetic function (which will be defined in the talk). We use this algorithm to establish some explicit upper bounds for the sum of divisors function.

This is a joint work with Zachary Friggstad (University of Alberta) and Robert Juricevic (University of Waterloo).

LIST OF SPEAKERS

- Open problem session*, 6, 10, 16, 19, 22, 26, 29, 33, 37,
41, 45, 48, 51, 56, 59, 62, 65, 69, 72, 76, 80, 84
- Adam Felix, 61, 70, 73
Adam Tyler Felix, 62
Akshaa Vatwani, 42
Alexandra Florea, 9
Alexev Popov, 56
Alexey Popov, 52
Alia Hamieh, 40, 45, 49, 53, 56
Allysa Lumley, 19, 27, 33, 67
Amir Akbary, 17, 23, 26, 29, 38, 47, 49, 57, 63, 66,
75, 76, 81, 86, 87, 90, 92, 94, 97, 101
Amir Akbary and Dave Morris, 92
Amita Malik, 18
Amy Feaver, 56
Anders Södergren, 61
Andrew Fiori, 17, 28, 35, 38, 42
